Hey, doubtful he's still taking in comments on a month old de-trolled post that has been nixxed by every usenet server in the universe...except yours.

You could have probably gotten a place of presence on his Website, maybe a photo?. No wait...that was also wacked a month ago. You weren't quick enough. Dammit.

Don't respond to trolls unless you can do it with good comedy within 24 hours....unless you are like me and will reply to anything.

Hi All,

Anyone recall or have a copy of the articles in Ham Radio, QST, or 73's which has the 455KHz FM detector and the other information for Cb conversion to 10m FM?

I recall that Melco did some kits, I recall the article but can not locate it in my library.

I believe I saw a FM demodulator either HR or HR Horzion.

thanks de KJ4UO.

Are those things specified for RF? I wouldn't touch them with a 10-foot
pole if they aren't. If you're planning on tuning by switching elements
in and out have you considered PIN diodes? If you have them either all
the way on or all the way off they should be less susceptable to IMD
than varactors. Furthermore, I understand that if you're cheap you can
use the old 1N400x series of power diodes at HF (I haven't tried this,
though).

There are a number of video cards with a NTSC video output in the
S-video format. I still have a couple I used in old PCs to drive a
Commodore 1701 monitor to trick people. My Commodore 128 was connected
to an IBM PC Junior monitor in CGA mode. The look on people's faces was
worth the effort.

It acts as offset quadrature PSK with the bits weighted to be 1/2
cosines instead of rectangular pulses. You decode it just the way I said.

If you can find them the following two papers are quite useful. One of
them (the one from the IEEE Comm. Soc. IIRC) is easy enough that you can
just about design a demodulator straight from the paper.

[1] R. De Buda: "Coherent Demodulation of Frequency Shift Keying with
Low Deviation Ratio" -- IEEE Transactions, 1972, COM-20, pp. 429-435.

[2] S. Pasupathy: "Minimum Shift Keying: A Spectrally Efficient Modulation" -- IEEE Communications Society Magazine, July 1979, Vol 17, #4, pp 14-22.

And if you live in Worcester, MA, and you're wondering why I know:

[3] Tim Wescott: "A DGPS Radiobeacon Receiver for Minimum Shift Keying with Soft Decision Capabilities" -- Master's Thesis, Worcester Polytechnic Institute, 1990.

Stop by the library there -- I believe they'll have a copy.

Here's a summary of the reasoning (taken from Chapter 3 of [3] -- I like the author). This is much better with pictures (the clearer paper of [1] and [2] uses pictures, as does [3]):

The way that MSK works is to have FSK signal with a frequency shift that is exactly 1/2 the baud rate. Thus the phase shift from one bit time to the next is 90 degrees (1/4 of a circle).

Now consider a quadrature, offset PSK with 1/2 cosine weighting (really, do). Thus even-numbered bits are transmitted as either positive-going or negative-going cosine waves multiplied by the carrier, each one lasting for exactly 1/2 cycle of the cosine, and the cosine having a frequency of (bit rate/4). Odd-numbered bits are transmitted as either positive-going or negative going _sine_ waves multiplied by the quadrature of the carrier.

Take your bitstream, and make two signals a_i(t) and a_q(t). The signal a_i(t) is +1 if it's corresponding bit is 1, -1 if the bit is 0, and it only changes on boundaries of t = 2*k*T where T is the baud rate and k is the bit number. The signal a_q(t) is similar, but it changes on boundaries of t = (2*k+1)*T.

Then the transmitted signal is equal to

s(t) = a_i(t)*cos(pi*t/(2*T))*cos(2*pi*f*t) +
a_q(t)*sin(pi*t/(2*T))*sin(2*pi*f*t) (1)

where f is the carrier frequency (1200Hz in your case).

If you grind through those high school trig identities (1) becomes:

s(t) = cos(2*pi*f*t + b(t)*pi*t/(2*T) + phi(t)) (2)

where at any given moment b(t) = a_i(t) * a_q(t) and phi(t) = (a_i(t) + a_q(t))*pi/2. Assuming I haven't messed up my expression for phi(t) (the value I gave for it in my thesis is clearly a typo, I'm guessing here) this is a phase continuous FSK signal who's frequency is the carrier + 1/4 the baud rate for two consecutive 1's or two consecutive 0's, and carrier - 1/4 baud for a 1 followed by a 0 or visa-versa.

That's what MSK _is_, from a OQPSK sense, there's more about demodulating it -- let me know if you can't find the articles, or anything sensible on the web -- I'm thinking of scanning this stuff in...

Come to think of it, yes, my ATI all-in-wonder card can do that.
It has the S-video jack. One of my oldies but moldies was Genius Video
from Kye. It plugged into the auxilliary connector of the SVGA card
and allowed an NTSC compatible capture, with NTSC in/out RCA connectors.

It has been so long since I have used them I totally forgot!

But Dan THAT would make too much SENSE! (grin)

The trouble is that the unattended robot train has already left the
station.
ARRL deliberately did this without carefully coinsidering the monster
that they created and now that they persuaded the FCC to go along
with it, the problem is too late to remedy.

One can only hope that they will learn from this horrendous blunder.
Looking at the latest proposal from this same committee, (segmenting
by bandwidth only) I see only more stupidity being foisted on a
majority by a small group in a smoke-filled room.

Most of us are finding out what they did each time, only after the
damage is done.

WHERE is even the basic polling of radio amateurs?
Did they ask amateurs in other countries that will be affected
by this?

Do 40m CW ops REALLY want to be HEMMED IN to the bottom 35 khZ?
OK the rules don't SAY that will happen, but if you give the
Mexican and VE SSB pests and the digital ops and MORE rope than
they have already taken, 40m CW could become a thing of the
past.

YMMV

I assumed you contacted your ARRL division director to make your views known? That's the mechanism by which decisions they make get input from everyday amateurs, so those amateurs' views can be represented in the "smoke-filled room".

After the ARRL's decision, how did your director explain to you how and why the decisions were made?

Or do you just sit and grouse and not bother to make your views known to someone who can actually do something about it?

P.S. If you identify yourself to your ARRL director only as "The Old Man", he's probably not going to pay much attention to you. And rightly so.

Hi Tim,

I use 1N4007's or 1N4004's as a drive control in 3 homebrew transceivers but never for switching. I have used PIN diodes for the same application I am considering the SSR for. I looked at the the MosFET SSR's because I have usedIRF510's and IRF740B's to cathode key my tube transmitters. I was expecting that a MosFet relay would likely work in a similar manner to switch xtal converters for bandswitching. I chose the IRF740B for keying my TX due to the VDS of 400 but most due to low RDS > 1 ohm. The low price SSR have avg of 22 ohms but with low current that may not be a big minus. For a $1 to $3 investment each its worth an experiment.

Some are specified for RF up to Ghz but most SSR's for sensing and power control. And they are pricey.

I am really just looking for something different to switch convertors for 20 and 15 M on homebrew tube rx. I didn't comment correctly above in my reply. After I read it again he was looking for a way to tune a band pass filter and i am trying to switch a complete circuit. But I did look at the varactors too but that was when I considered premixing for the LO and tuning the front end. Gotta admit I have been building with tubes a long time.
I just didn't want to use plug in coils.

I looked at your web site and I know Worsester, MA. I was born in Newton and my dad went to MIT.

Don

No; that connector is useful only for hookup of a factory test rig.
Someone was selling an outboard CPU module on eBay a few months ago that
had a GPIB port; it went for big bucks, and it was the only one I've
seen in probably 7-8 years of watching the market.

You will need to trade up to a P-suffix model for any type of data
acquisition or digital plotting.

From my perspective, I can copy CW very well with a narrow filter, even
with a large amount of QRM from a digital system.

And, the digital system is probably not going to be able to deal with
my interference half as well as I can deal with its.

Since I am reading this on rec.radio.amateur.boatanchors, where it is
crossposted, may I recommend the use of the audio filter on the Collins
R-390A? It is frighteningly effective at getting rid of this trash.

HR magazine for Februari 1983 had an article on CB to 10M FM conversion
written by VE3AQN and VE3FIT, 7 pages in total.
Will copy and E-mail to you on request.

Well there was an article in QST by Bob Heil about converting a CB set
to FM, I'm pretty sure it was in 1981.

As I said here back in 1998:
Converting a CB set to FM, once the conversion to the appropriate
section of the 10M band has been accomplished, would consist of FM'ing
the transmitter (I can't remember, but I assume the articles disable the
AM modulation of the final amplifier, and feed some of the audio to
the VCO), and adding an FM detector to the receiver. The two articles
I can remember used IC detectors, which would add some IF
amplification and limiting before the detector. One thing worth
considering is that you can easily scrounge up a 455KHz FM IF strip from
a cordless phone, or a 49MHz superhet walkie talkie.

I wouldn't say fidelity is an issue here, given that it's narrow deviation
we are talking about and that's not a problem to get a linear discrimator.
YOu probably will get a better results with a full FM IF strip, and those
are really easy to pull from various things, either just the IC (any old
TV set will have one for the sound demodulator, at least in North America),
or for that matter any FM "stereo receiver", or as a full IF strip. The
advantage of the latter is that the discrimator is already aligned, and
you get not only the demodulator IC but the needed IF transformers and
FM-bandwidth filter(s).

You can find such strips in cordless phones (I found some a few weeks ago
that were for 2.4GHz, and they still had defineable IF strips with 10.7MHz
and then 455KHz conversions), or those 49MHz walkie talkies, or older
cellphones (which have the advantage of being cheap and don't have high
integration in the ICs). I've never found a scanner in the garbage, but they
too would have such IF strips. Even commercial 2-way equipment had such
IF strips, and even recent ones may (though since I'm not familiar with
recent equipment I don't know if they are still going down to 455KHz.)

>known?

Good answer, Roy. But I'm pretty sure that "The Old Man" isn't a League
member, or if he is, he takes no part in his Section. He said:

>> Most of us are finding out what they did each time, only after the damage
>> is done.

Certainly I heard about it well before hand, and expressed some concern, in
this case to our vice-director who happened to be dealing with this
particular issue. I got some additional feedback which reduced, but did not
eliminate, my concerns.

I suspect if "The Old Man" was on the radar of his section or division folks
as someone who was reasonably active, he would have had plenty of
opportunity for input early on. Most directors send out emails about stuff
like this to anyone in their division they suspect is active. Actually, if
I recall there was even a mention of this happening in QST well ahead of
time, but there is a lot of stuff in QST and something like this is easy to
miss.

Most folks, though, would rather bitch than take a few minutes to educate
their representatives. Kind of a shame, really, that so many folks can
spend so much energy bitching, but are unwilling to spend even a little
energy to make amateur radio better.

A frequency-hopping spread spectrum system with a reasonable amount of error correction won't be bothered much at all by iCW, as a matter of fact. :-)

Dittos. Also most electrically tuned circuits suffer from lower Q
and strays. It is hard enough to build hi Q cavities let alone try
to emulate one. It might be more worth while to build a motorized
cavity or electrical band switching of helicals, but who has room for
all that? Many manufacturers have concentrated on making RF stages
that can withstand very high levels without intermod. Of course none
of this will help you if you are at a congested site with mixes in
transmitters without circulators.

At HF it is practical to build a bandswitched set of bandpass filters
much like the ones found in some radios. Toroids can make them small
enough, but again you need to be careful not to overload them.

Without software, no. When I built the radio for my thesis I started with an analog demodulator which occupied a 4.5x6 inch prototyping board -- I think it had 6-12 chips on it, and it had problems with thermal stability which is why the final version of the radio used a processor for the demodulation.

I'm eyeing my thesis, and my brand-new scanner. I keep thinking "36 pages? NO!". If I get the spare time I'll scan this in but right now I have a shortage on both time and round tuits.

You indicated on another one of your postings that you had found a suitable FSK chip -- this will work for you, but with far more noise sensitivity. But: if you started with that chip you could get a working device _now_; later on when you got all of the other bugs worked out you could circle around to the detector and upgrade it to something better.

What's this for, by the way?

Switching on the speakers is risky. I have actually just paralleled the outputs of radios and stereos at the speaker with no problem as long as everything was DC blocked and the voltages present never exceed what the PA stages could handle.

I also did this by building a mixer stereo preamp that would take input from earphone jacks from an HT and portable scanner into the car stereo after its own volume control. The source radios had their own volume control and the stereo had its volume control. All this so I could run in a pickup truck. I had no muting, but this could be done with COR switching of mute gates.

An aftermarket add on may be more viable with stereos that have preamp outputs to various amps, but COR usually needs to be brought out of the radio.

I do remember seeing such a thing but not lately. It was activated by RF sensing so only muted when transmitting.

Yes, but a frequency hopping system should recognize that this individual
channel is currently not good, and stop using it!

Try Waters and Stanton.
I have just ordered a copy yesterday. I checked by phone that they had some copies in stock. The RSGB appear to have sold out and no longer have it available at radio rallies.

Well, that's news to me! (The W&S part, that is. I knew that RSGB and
ARRL had both sold out some time ago.)

Please let me know how it goes, because people do ask from time to time.

If it can, certainly... but it's the standard "near-far" problem in that you
may be able to hear the interferer (the FHSS system) but he can't hear you.
:-(

3046. CB -->6M Conversion?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-30 21:23:03 UTC
From: Dale Parfitt <par@parelectronics.com>
Message-ID: <XoZwe.14723$gm6.1600@trnddc05>

After seeing the post re CB to 10M FM conversion I got to wondering if anyone is aware of a conversion for the Hy Gain 02A boards to 6M AM or FM (Melco and many others used this board for the 10M FM conversion). I still have some boards left.
I built many of the Melco kits years back and another from HR or 73 that has 10M digital readout, noise squelch and repeater splits- still have the rig and in use.

That would be quite a bit more difficult -- Going from 27MHz CB to 29MHz amatuer radio bands is just a 10% frequency change. Going from 27MHz to 50MHz is almost a doubling, and with older components it may require not just different component values but even different circuit topologies to make it successful.

But it would be interesting if anyone made it work...

Yes, there was such a conversion article in "73", I want to say 1982, but
it might have been a year or two later. That's as specific as I can get.

The premise was that since the CB sets had high side injection, the image
was close to the 6meter band. YOu had to modify the output circuits of
the transmitter, and the front end of the receiver, but the PLL was almost
there. A shift of a few MHz, if I recall, and the solution I'm picturing
is a putting in a crystal oscillator to mix the VCO down to frequency
where the variable divider kicks in. (As standard, again from memory,
the 10.240MHz oscillator that is divided down to be the reference in
the PLL is normally used in this premixer.)

I seem to recall some years back finding a bibliography of all those
CB to ham conversion articles somewhere on the internet. It might
be worth doing some searching to narrow down exactly when that 6M conversion
article was.

Something for those who want to do 6 meters on the cheap.
I have NOT tried this as I have yet to find a CYBERNET chassis to
work on that has not been "screwdrivered" by someone else.
This conoversion should work on all PTBM49A0X AM/SSB chassis boards.
This includes the :SEARS 60006
HyGain V
RCA CoPilot (14t302)
Citizen M-6 /MPL-5
DAK Mark X (ten)
Midland 6006
When I can find something to do this conversion on,I will post my
results.
If I can find or come up with any other mods for 11 to 6 conversion I
will post those.

CONVERSION BEGINS:excuse the typos,original authors.
___---
CYBERNET
From: VK3KAY@VK3IBM.VIC.AUS.OC
hello all
here is the mod for taking 11 metre cybernet radios to 6 m
as i have been asked by many people for it
so here it is:

Pearce Simpson Model A18
Conversion to 6M SSB
by VK4FXX / VK4ZGF

Here is 6M mod for Pearce Simpson Super Panther and other brands using the
Cybenet type circuit board. (Digital channel readout prefered)

****** Ensure CB is working correctly before starting mods ******

Replace X1 Xtal with one of the following of your choice....

10.97625 Mhz ..... Band 52.050 - 52.480 for 40 ch switch
10.15175 Mhz ..... Band 50.020 - 50.240 for 40 ch switch

Band 52.050 - 52.480 / 10Khz channel spacing ....

Xtal freq = (Freq TX - 10.692) + 2.55

Band 50.020 - 50.240 / 5Khz channel spacing .....

Xtal Freq = (Freq TX - 10.692) + 1.275

4

Receive Section

C 100 Replace with 8.2pf- 12pf until T7 peaks (see alignment)
T 8 Remove internal tubular cap and replace with 8.2pf on back
of PCB
T9 Same as T8
T7 No mods required
C 104 Replace with 1.8pf cap (all caps disc ceramic low voltage)

TX Section

C 42 Replace with 1.8pf
C 185 Remove (no cap)
C 47 22pf
C 53,54,55 By experiment can be varied from 100 - 150 pf fpr max tx OP
C 56 22pf
C 57 56 pf
C 184 Remove (no cap)

Coils and Transformers

T4,T5 Remove internal tubular caps and replace with 8.2pf under PCB
T 6 Leave same
L7 Leave 1 3/4 turns left
L11 Leave 2 1/2 turns left (remove one turn)
L13 Leave 1 1/2 turns left (experiment)
L12 leave 4 turns left (remove one turn)

L201 remove and replace with straight wire link (rear of SO 239)

CYBERNET.1
Final Transistors

Replace Q9 with 2SC1306 / replace Q10 with 2SC1307 fpr 10 watts OP
Original transistors will give approx 5 watts OP

PLL Alignment

Test gear required

Freq counter to 60 Mhz, Digital VOM, 15Mhz CRO

For 50 Mhz only....earth pin 4 of PLL 02A for 5Khz steps
Connect counter at TP2 through 1000pf cap and adjust CT3 for 10.240 Mhz

Connect CRO and counter at TP3 and adjust T3 for max amptitude.
Counter should show Xtal freq X2 (USB only)
Set clarifier at mid position
Adjust CT1 and CT2 so that TP3 reads 21.95272 approx on counter

FREQUENCIES AT IC2

Pin 4=21.95272 reference osc input
Pin 2=19.40272 vco input
Pin 9=2.55 approx loop error signal

VCO Alignment

Connect VOM to TP1 and adjust VCO slug for the following.....

40 Channel 10 khz spacings CH1 2.8-3 volts
CH40 3.8-4 volts

40 Channel 5 khz spacings CH1 2.0 volts
CH40 2.8 volts
(Voltages not critical)

Receiver Alignment

Peak T7 T8 T9 for max received signal
Peak T1 T2 T3 for max sensitivity

Transmitter Alignment

Align on USB only.....Adjust T4 T5 T6 / L7 L11 L12 L13 for
max. power OP.

NOTE If set oscilates in TX with no audio mod applied, go back and
re-adjust T4 T5 (reasonably critical)

Check for equal OP on CH 1 and CH40

3051. PIC SWR meter - help!!!!!!!!!!

I'm looking for AA4FB' Project ,,PIC SWR meter". I find soft, but
I don't know where find a description, schematic and PCB. Could
anybody send me by mail these elements of this project.
ps.
This project is in ARRL archive, but only for members.

James Patterson KB5LF had an article in 73 Mag back in February 1985.
It also used the HY-Gain boards.
5 pages and I will scan on request.
See my E-mail address under the CB to 10 listing.

Hi Group,

Radios like my FT-757 and FT-101 have an IF output. If I take this output to a spectrum analyizer and the SA center frequency is set the same as the IF frequency, will I have a spectrum monitor which will display over the complete bandwidth?

If so, is the BW of an IF generally large enought to view the complete band?

You'll see the IF bandwidth if the SA is set that wide or wider; otherwise, you'll just see the SA bandwidth.

Most receiver IF bandwidths aren't particularly wide; some are, but they're designed for it. The receiver specs may (and, IIRC, typically do) show IF bandwidth.

>output to a spectrum analyizer and the SA center frequency is set the
>same as the IF frequency, will I have a spectrum monitor which will
>display over the complete bandwidth?

While it will obviously depend on the particular radio, a lot
of rigs take their output from in front of the first IF filter and
so can diplay several MHz either side of center. My Kenwood
TS-850S(AT) and HP141T combo works fine in this way.

Cheers - Joe, G3LLV

This is an export transformer, meaning it is set up for 100 volts or so primary voltage. I was planning on using the HV section on 115volts for a single tube 3-500Z amp but have not gotten around to it. Wires have not been soldered - brand new.

Win -

Well, first you need some good RF relays for QSK.
You can use vacuum relays (Kilovac or Jennings) - MaxGain; Surplus Sales or
Fair Radio Sales
http://www.mgs4u.com/relay.htm
http://www.surplussales.com/Relays/REVacRel-1.html

and/or a fast RF reed relay like the Matsushita 1mS device.

Thanks, Greg. Actually I picked up the relays and other parts from
Richard (somis.org). Now I am just thinking about where I will put
the circuits. I am thinking about putting most behind the meters over
the filiment transformer, and those associated with the relays under
the chassis where the old relay will be removed.

I was just looking for ideas from those who had layed this out before
me in this amp.

Read your QRZ bio. Me, too, 40 meters CW..........

Thanks

Well 40 meter CW is where I started over 30 years ago ..
when the Novice band was 7.15 to 7.20 !! Can't wait till the broadcasters
will move -- will be a first class early evening DX band (sans static!)

I did see a couple of Internet web pages with the conversion -- but those
web pages are now gone - I'll keep an eye open. I think Richard did do a

conversion on an earlier SB-200 ... you may also want to look at the Ameritron/MFJ QSK-5 PIN diode internal board approach (for ideas how or how not to do it).

I usually do a small amout of soldering at once. I was thinking of getting a recharable soldering iron just for the convience factor. I was hoping to get a brand and supplier recomendation. I've seen them for around $60. I would think they would be fine for QRP type construction.

Richard did an article in QSt many years ago on QSK for the SB-200.
But, as I am sure you know, Ameritron is well represented at the ARRL.
Somehow that articke is no longer in the archive.

>w9gb

Richard did an article in QST many years ago on QSK for the SB-200.
But, as I am sure you know, Ameritron is now well represented at the
ARRL. Somehow that articke is no longer in the archive. I guess
articles on modifications to old amplifiers does not sell new
amplifiers.

Anyway, I think I have it figured out. Both of the connections to the
cathode bias swicth will be on the HV power supply board. I will just
place my circuit in proximity to that board. I will place the relays
where the old RF relay was. Should you come across anything, I would
like to see it, though.

In the early 60s I was rock bound to a DX-60 on a 40 meter dipole.
The receiver was an SX-101. I remember having a cigar box of rocks,
and tuning up and down the band after every call. It was a big thing
when I got my first, not so stable, VFO. But, looking back, those
were great days. I don't get the kinds of QSOs today I did back then.

Thanks again

Win, w0lz

Years ago, Wahl (the hair clipper company) made one that was small, lightweight, quite well made, and one that should suit your purpose very well. You might check to see if they still make it.

I wanted a portable iron for outdoor soldering but it didn't have enough moxie for outdoor antenna work. A butane iron is much better for that purpose.

==========
Suggest you consider a butane gas iron with choice of a number of tips with integral cathalitic burner . Gas flow can be adjusted ,hence the tip's temperature.
There are various makes . I happen to use the Portasol Professional iron ,made in the Republic of Ireland, but there are other cheaper but equally effective makes.

The iron's gas container with shut-off valve can be filled with a butane gas cannister as used for cigarette lighters.

The smaller tips are excellent for printed circuit boards involving ICs and the usual discrete components.
The larger tips are good for more heavy work like soldering PL259 plugs to coax .
A 'Jumbo' tip has an equivalent rating of 100 Watts
However for surface mount components you need a micro tip. For this type of work I use an electric cordless iron powered by 2 pcs 1.2V NiCad batteries. But after a number of joints the batteries must be charged by placing the complete iron in a stand . The unit I use is called ISOTIP ,made in USA by Wahl Clipper Corporation.
The iron was purchased in 1980 and used regularly ,however the charger is very primative (just a transformer with an embedded diode in the secondary low voltage winding), resulting in relatively short battery life . I now use the iron with a homebrew charger permitting 2 selectable charge rates being 300 and 10 mA , the first used while using the iron , the 10 mA rate when idle (trickle charging). Now the batteries hold their charge well and the iron is ready for use at all times . Battery replacement however is awkward .

Frank GM0CSZ / KN6WH

That sounds like the one I had in the 80's. It soldered well enough but
didn't have enough gas in the battery tank to do any very serious work.
If it were to be used regularly Frank's comments about a trickle
charger are worth noting.

Wahl Corporation's HQ is about 100 miles due west of my QTH (outside of
Chicago).
http://www.iso-tip.com/html/soldering_irons.htm

They sell both the Iso-Tip cordless as well as an EZ Change model
Here are the web pages:
http://www.iso-tip.com/html/cordless_irons.htm
http://www.iso-tip.com/html/iso_tip_accessories.htm
http://www.iso-tip.com/html/ez_change.htm

They also sell a line of butane irons
http://www.iso-tip.com/html/butane_irons.htm

I have two of them, picked them both up at a hamfest for $5 each. Though they needed batteries and a tip, they - to me - were a steal.
All included, I got both for less than the price of one - new. I use mine extensively at times and got them for times when I'm trying to do repair work when no immediate electric source OR as is my luck, a damned storm comes and knocks out the power. At least with the Cordless, I can keep on working. Most of my work involves only a DMM and Soldering equipment, anything else can wait til power is available. I was able to get "very" small tips for the really fine soldering I do at times, saved me lots of grief. These are Iso-Tip brand. Very easy to maintain too. Not much to go wrong with them. Tip and batteries - two major parts, aside from the transformer in the charging base.

Even if ya have to buy one brand new, go for it..... "I" feel you'll make a good choice. Before I close out - I "do" hope you're referring to the "hot" kind, not the cold!!!!! The cold are JUNK.

Add a 1N4000 (or similar small power) diode in series with the lamp
to extend the life. I was replacing the bulb every couple weeks, till I
did this.

I had the Wahl orange, eight hour charge version. I added a switch
to the primary of the transformer to turn it off at night. It rarely
ran down in normal, day to day use, and I worked at least 40 hours a
week with it and a couple other irons on my bench.

PS: The first version was gray and took 16 to 24 hours to charge. The
orange model came next, followed by the red, one hour charge model. Of
course, it came out the week after I bought the orange one. :(

I did, for about 12 years. Finally, the transformer went bad, and
the third battery pack shorted out. It was starting to develop cracks
in the iron's body, so I reluctantly salvaged the only good parts, the
diode and the bulb.

> How do you measure the impedance of a broadband transformer for a RF
>transistor amplifier? I'm referring to the input and output broadband
>tranformers just before and after the transistor finals.

With a broadband network analyzer and a set of resistive
terminations...over a wide bandwidth of frequencies. To be
very precise. But, you don't have to be that precise.

It's no different than checking an old audio transformer, such as
a vacuum tube output amplifier's transformer. Just count the
turns in each, square the ratio of the number of turns, and
you have the "impedance ratio." That's a rough approximation
which usually works well for most things.

All the answers depend on what you want to find out about this
solid-state RF amplifier. Please give more details on desires.

Most of the Motorola App-Note designs are detailed enough to
get the data direct, including designing your own particular
broadband transformer thingy. Helge Granberg did a nice job
very detailed in those App Notes.

Hi, all concerned:

I have 3 old, well-used Wahl rechargeables and charger-holders: 2 black "slow charge" units, and one orange "fast charge" unit. I used the beejeebers out of them in my spare-time-electronic-repairs-shop days.

New Wahl tips, batteriesamerica.com replacement solder-tab nimh C-cells, and some charger mods to work around the evils mentioned below, would rejuvenate them nicely.

Best offer gets the lot, and pls include $6 for shipping in your offer.

Tks for reading.

Ian,

It is a brilliant book. My "dog-eared" copy is now falling to pieces through overuse;-(

I suppose that times have changed and a reprint is now out of the question.

Would you, or any of the contributors, object to somebody putting it up on the internet, i.e. as PDF files in the same way as the Classic EIMAC "Care and feeding of power grid tubes" is?

Best wishes and thanks for "The Book"!

Pulled a high speed vacuum relay, Jennings RJ1A, out the other day that I was saving for a QSK mod to my old amp. There is component across the windings of this relay that I can not identify. It is soldered, or silver soldered, to the winding terminals. It is about 3/16 square, yellow, and has the following markings: JAVX 8652 AA M390 14/01 1553.

Here is a slightly out of focus picture.

It's a rectangular ceramic cap, _possibly_ 39pF ('cause of the "M390"
marking). Those things have military catalog numbers and don't
necessarily include the actual value printed on the cap, which is a pain
if you have a mixed bag of them, or if you have one on a board and want
to know it's value.

Thanks, Tim. I think you are correct. Rich Measures, KG6K, said it
could be an MOV, which is a capacitive device.. What eve it is,
exactly, I think I am going to leave it in the circuit. I can't see
it hurting anything.

3090. Looking for Specialty Crystal Filter, Please Help

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-05 15:30:31 UTC
From: ZenSafari <chris.rehorn@gmail.com>
Message-ID: <1120577431.428234.246660@g14g2000cwa.googlegroups.com>
Source record: 18273

I am currently looking for a crystal filter in the CF range of 70 to 100MHz. I know that these are rare and are not standard for FM radio, citizen's band, etc, but it would be most helpful for me to find one. Ideally, the filter should have a passpand of +/-3.75kHz about the CF (3dB). I've checked numerous manuf. who make these type of crystal filters (FOX, ILSI, Raltron, MCF, etc) but most of their products are vapor ware and have never been fabricated. Do any of you have a suggestion of where I might find a filter that meets this spec? My goal is to avoid another IF stage in my hardware...this is why I require the narrow bandwidth at the high CF. Even if you have a suggestion of where I might find a 70 to 100 MHz CF filter with a wider bandwidth I would appreciate it very much.

Thanks for the help.

The only off the shelf 70 MHz CF filters I've seen were used in
Satellite TV or Telemetry receivers. Microdyne built their own IF
filters For narrow frequencies like this, with switching to select one
of up to 12 internal bandwidths, and a few models allowed 12 external
filters, as well. The SAW filters for Satellite receivers is generally
+/- 10 MHz, so those won't help you. Its too bad, because there are old
C-band and early KU band junkers almost everywhere.

Chris-

I recall such a product from about 25 years ago, but for the 155-165 MHz
range and somewhat wider bandwidth. It was from:

PTI - Piezo Technology, Inc.
http://www.piezotech.com/
2525 Shader Road
Orlando, FL 32804 USA
Phone: 407-298-2000
Fax: 407-293-2979

It might be worth contacting them, in case they still make the filters,
and can make them for your frequencies and bandwidth.

73, Fred, K4DII

I have a couple of the Ten Tec filters that were used in their Paragon transceiver. 70 MHz center frequency, don't remember the bandwidth but could measure one. Or you could check with Ten Tec and if it fits your requirements, they're available.

3095. Polarity of 2SC1970 and 2SC1971

Newsgroup: rec.radio.amateur.homebrew

Hi All,

Two RF transistors, 2SC1970 and 2SC1971 are supposed to have BEC pinouts according to data sheets. However, it seems that such transistors with BCE pinout also exist; resistors in one circuit caught on-fire when I plugged a 2SC1971 into a BEC socket (based on data sheets, I assumed the transistor had BEC pinout). After replacing the resistors and bending the leads of the transistor, the circuit worked properly. Yes, the socket was wired correctly for BEC pinout. Has anyone ever come across the BCE pinout versions of 2SC1970 and/or 2SC1971?

C.W.

==========

According to Tower's International Transistor Selector , both 2SC1970 (Ic max=0.5A) and 2SC1971 (Ic max =1A) are NPN RF power transistors in a TO220 package
Pinout 2SC1970 is BCE
Pinout 2SC1971 is BEC

The above pinouts are confirmed by the (PDF format) datasheets which I found by doing a Google.

I think we would all be interested in what you discover. My own reaction is
that you're not going to find something that narrow at that IF, but if you
do, it might be useful in other contexts.

Scary!

I have noticed some with tabs isolated and some not. Gotta check the spec sheets. NTE replacements worked fine in TS2000 and are probably re-marked OEMs.

Analog VOM would help.

Hello Art,
This is only our second annual hamfest. Last year it was held in August, a day after the hurricane came thru. Our turnout was only about 300. Feedback so far this year says we should have between 500-750. Good odds for winning a door prize or the main drawing.
Worst case, we're only 6 miles from the 9/11 Flight 93 Crash Site / Memorial. That in itself would make the trip worth it. The Somerset

Somerfest is also running from Friday thru Sunday. Food, Music, Fun... I should work for the Chamber of Commerce...HiHi

Hope to see you here.

Why pay $10 for information you can get for free from many other sources?

3103. New program. Two SWR meters

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-06 23:17:09 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <dahopl$110$1@nwrdmz03.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 18286

This program models the behaviour of a transmission line plus antenna.
The line impedance can have any Zo. The antenna feedpoint impedance
can be any value of R+jX. Line length can be any fraction and number
of wavelengths. Line overall attenuation can be any value of dBs.

There is an SWR meter located at each end of the line. The meters also
indicate the reflection coefficients at the locations. Meter Zo can
be set equal to line Zo or to the standard 50 ohms.

Line input impedance can be observed to change versus line length in
wave-lengths, line attenuation and antenna impedance. The transforming
action of the line can be demonstrated. The smaller SWR and reflection
coefficient at the transmitter end of the line can be seen. The exact
increase in loss due to standing waves on the line is calculated.

The program can be used in practical applications and also for
educational purposes. It is hoped it may prevent the outbreaks in
violence which frequently occur in newsgroups about the meanings of
SWR and the notions of reflected power.

Download program SWRARGUE from website below in a few seconds. File
size = 41 Kbytes. Run immediately. No unzipping inconvenience.

3104. A DRM converter for Icom RTX

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-07 08:59:21 UTC
From: PaoloC <ollollo@hotpop.com>
Message-ID: <42cceeaa_2@x-privat.org>
Source record: 18287

Hi.

I have successfully built a 12kHz downconverter for Icom (T)RXes that use a 2nd -and last- IF at 9MHz. The adapter can be used to receive DRM HF broadcasts with commercial HAM rigs/RXs and plugs on the optional filter socket (no soldering required).

Some devices that can mount optional 9MHz filters are:
IC-706/MKii/MKiiG, IC-725/726/728/729, IC-735, IC-R70/71/75 receivers.

A first test with a balcony homebrew antenna (http://spazioinwind.libero.it/ik1zyw/temp/IMG_0030.JPG) and an IC706MKiiG allowed me to receive bitXpress banner on 15.896 MHz and listen to Deutsche Welle on 6MHz broadcast band. I used "dream" software on Windows.

The same downconverter can also be used with SDRadio (http://www.sdradio.org/, without sideband rejection) in order to accomplish narrowband filtering, or SSB/CW/FM demodulation for some receivers (such as IC-725/728 that require an optional unit for FM reception).

I will soon carry on further reception tests as well as side-by-side comparison with 455-12 DRM converters on other receivers.

If there is enough interest I will publish a complete description of this downconverter, including the design involved. - unless I receive an offer to buy the whole project :-) -

Greetings,
Paolo IK1ZYW

From: Just Cuz <JustCuz.Not.A.Real.Address@hotmail.com>
Message-ID: <spmrc1pbv0dd5ldstj3gks3eimllc1crsl@4ax.com>
Source record: 18289

I have been looking at a variety of RF transistor amplifier schematics including a 50 watt amp shown in the ARRL handbook (1996 - page 17.96) , and they do not have emitter stabilizing resistors and ac by-pass capacitors on the emitter leg of the final output transistors. Is there a good reason for not using emitter stabilizing resistors and ac by-pass capacitors in 100 watt output or more RF transistor amplifiers?

Here are some on-line schematics I found of high power RF power transistor amplifiers, and in all of them the emitter goes straight to ground.

My hunch would be that most of those amps probably use ballasted emitter transistors which mitagates the need for an emitter resistor. That, plus the fact that any impedance in the emitter lead is an invitation to oscillation, and obtaining a good low Z bypass is tough at HF especially at the current levels involved.

I seem to remember two trimmer caps so I guess there were a total
of four tuned circuits. I think the ham radio article I saw on
converting the rig did add a bfo using a tv horizontal coil cut
down as the bfo coil. I could also remove some wire from an old
BC453 bfo coil, of which I have a few in the junk box. (Not to
metion about a dozen 85khz if cans).

Which reminds me.....
I was thinking of building a solid state version of the old
Drake 2B receiver with it's 80meter first (tunable) IF, 455khz
second if, and 85khz third if (using Arc5 IF transformers) instead
of Drakes 50khz (close enough). I'd use a BC454 tuning cap padded
down to cover 3.5-4.1mhz just like Drake. The first oscillator
would be a PLL to cover everything (beats grinding on ft243 rocks).

>

> vacuum-to-solid conversion.
Junction fets are rather low gain, though compared to tubes with
28 volts on their plates, probably a good match. The cascade circuit
can be built with either two jfets, or one jfet and one bipolar. The
jfet/bipolar version combines the high gain of a bipolar transistor
with the high input impedance of the fet. That's the reason I'd give
it a try (plus I enough of BOTH kinds in the junk box). I'd replace
the converter tube with three fets, two in differcial for the mixer,
and one for the oscillator.

Well that doesn't take into account the distributed capacitance of the
coil windings, which would be considerable at this frequency what with
the required inductance. (ever wonder why a grid dipper covers a much
higher min-max frequency ratio as the frequency band goes up?) Also
IIRC there are trimmer caps in parallel with the tuning caps for
alignment as the coils are fixed. To make the oscillator track, a
series padder cap is used to reduce the max. capacitance value of the
oscillator section. -OR- a parallel padder could be used to swamp out
the range of the section.

You can't get much power out of a tube at 28v on the plate. The 28D7
was up to the task being a double power pentode with the sections in
parallel (why not push pull?). I wouldn't call solid state conversion
canabilzing.

Information on and discussion of synchronous AM demodulators is scattered widely. There are sporadic discussions on a couple of Usenet news groups but they are restricted to text messages and it's hard to find the wheat in the chaff. This new group can accommodate schematics and pictures and provides a filtered view focussed on this one subject. In time, I hope that its collected files and discussions will make a strong starting or reference point for all with an interest in Synch AM.

Please join if you have ever designed or experimented with synch AM demodulators or intend to start. Visit the web site at http://groups.yahoo.com/group/Synch_AM/ to subscribe. Your designs, experiences and participation in the on-topic discussions to ensue will be welcomed.

Power burnt in the emitter resistor is power that isn't going out the
antenna. So it makes sense to use a fancier bias network and no emitter
resistor.

==========

Most RF power transistors in the 50-100 watt range already have an internal emitter resistor. It's usually less than a tenth of an ohm, perhaps only a few hundreths of an ohm. Its purpose is to prevent thermal runaway and make the device more tolerant of overload due to momentary impedance mismatches. Internal resistors have an extemely low inductance. They are NOT wirewound. They are an integral part of the transistor construction and material. The manufacturer may not mention their existence in his catalogue or data book.

RF power transistors are usually multi-emitter devices - all in parallel. Each emitter has its own individual series resistor.

Such low-value external resistors are not available as discrete wire-ended circuit components. Inductance would be too high at HF and an invitation to self oscillation. Don't attempt to use normal circuit components in emitter leads unless a transistor manufacturer specifically recommends them.

HF and VHF power transistors are very fast fuses. They are worked very close to their maximum voltage and current ratings.

From: Hernán Sánchez <nanchez@gmail.com>
Message-ID: <1120841226.098662.244630@z14g2000cwz.googlegroups.com>
Source record: 18295

Hi.

I'm planning to do an spectrum "visualizer" using a TV-Tuner (113-198c on www.tvetuner.com).

The basic idea is to undersample the IF output of the TV-Tuner and do some digital process to that signal with a DSP.

I want to know the IF level on those tv tuners, I mean, the output impedance and voltage level. I haven't found that info in the datasheet I have for that tv-tuner.

Thanks

Hernán Sánchez

>the range of the section.

As an aid to setting a tuning range, check out the February 1977
issue of Ham Radio magazine (under my byline). It covers adding
parallel caps, series caps, series-parallel and parallel-series
combinations. Easy formulas, all algebraic.

Worst case distributed capacity with typical inductances used at
this frequency might be 12 pFd.

Given a 32 to 352 pFd variable min:max, the C ratio = 11:1

Add 12 pFd to each section and C ratio = 8.0889:1 and F ratio =
2.8441:1. Add a total of 18 pFd in parallel and C ratio - 7.3800:1
with F ratio = 2.7166:1 and that is good from 190 to 516 KHz.

There's a near-infinite number of solutions for series-parallel
combinations for the LO but only a few will track adequately

with the antenna and RF amp stage. I suggest doing a simple computer program for that kind of thing. It can check resonance of the LO tank against the Antenna-RF tanks and find the difference in resonance at as many frequencies within range as you want.

>heathkit).

I understand that you may find it overwhelming, just because the Heath may be so simple, but the 564B is a really nice scope. It's only downfall is that it's only good to 10 MHz (and the 3A72 is only good to less than that.)

With a better plugin, like the 3A1 or the 3A6 this is a really versatile scope as long as you don't need higher bandwidth (and most people don't.) Your 3B3 is a good time base.

The nicest thing about the 564B is the fact that you can get lots of different plugins for it that do lots of interesting things, from 4 channels plugins to spectrum analyzers.

I'd encourage you to sell the Heath, but I'm biased. There's a 564B sitting just to the right of my PC. ;-)

I'm trying to build the simple AM receiver shown here:

http://www.electronics-lab.com/projects/rf/006/

The only modifications I've made are changing the 200uH inductor to a 100uH (ferrite rod) inductor. I'm using a 10-120pF variable capacitor (http://murata.com/catalog/t13/t13_09e.pdf), so I believe I should be able to pick up the higher AM frequencies (correct?). I haven't been able to get it to work yet (usually silence or static, sometimes a high-pitched buzz), and have a few questions:

1. One of the caps is labeled 100n. This would be the same as the other caps (.1uF). Is this a typo, or is the diagram just not consistant?

2. The first three voltage checks I'm getting withing a couple hundreths of a volt. The Q3(b) voltage (supposed to be 0.62V) is reading 7.06V. And the Q3(c) (supposed to be 3.87V) I'm getting 1.07V. Can anyone spot a connection error I might have made that would cause this?

Thanks in advance for any help on either question!
Dave

Something very fishy there with respect to the voltages at Q3. Notice that Q3-b is fed from Q3-c, so the potential there should be lower than Q3-c in any event. And if Q3 is OK and wired in correctly, since Q3-e is grounded, you can't reasonably have Q3-b much more than 0.7V above ground. It's just a forward-biased junction. So as a start, look for problems around Q3! Remove Q3 from the circuit, and check the voltage at the bottom of the 10k resistor...should be nearly the same as the battery voltage. And at the junction of the 560k and the 100nF, should be just slightly lower. Then if you ground the bottom of the 10k, the junction of the 560k and the 100nF should be zero volts. If it's not, perhaps the 100nF is bad (leaky or shorted). I'd say the 100nF (which is indeed 0.1uF) is way larger than needed in this circuit--100pF would likely be large enough.

The description says it's a "regenerative" circuit, but I'm not seeing any significant regeneration! Looks like a simple RF amplifier followed by detection in Q3's base-emitter junction, and Q3 amplifying the audio.

100uH and 10pF would tune about 5MHz, though stray capacitance and parasitic capacitance in the coil will make the net capacitance somewhat higher. 100uH and 120pF would tune about 1.45MHz, just the upper end of the medium wave broadcast band. I'd suggest you try for more inductance and/or more capacitance in the tuning system. For a quick trial, just parallel in 100pF or so; the tuning range will be limited but at least you'll be in the MW broadcast band more solidly.

Cheers,
Tom

Tom,
Fantastic, thanks for the help. I realized that one of the transistors was in backward, so that was one problem. The voltages are closer to those reported, although off by a couple tenths of a volt. I also put another 120pF variable cap in parallel with the first, so I have a range of 20 to 240pF. After some tinkering, I've managed to pick up a station. However, it's pretty poor quality (I can make out the words despite a constant, high pitched whine). I also used a 12k resistor in place of the 10k (as I'm out of 10k). So I'm led to a couple more questions:

1. The current circuit doesn't have an antenna. How could I attach one to this circuit? And what would be the best way to do so? (single

wire, x" long wire, etc?)
2. How much would attaching the circuit ground to a fence (or
something) help?
3. What might be the cause of the nearly constant background whine?
Is there anything I can try to fix it?

Thanks again for the help!
Dave

Dave,

Assuming the 100uH is a standard ferrite rod type antenna, you can likely give it a boost by winding just a couple turns (experiment: try from one to five turns, for example) of wire around it, grounding one end of that wire and extending the other end into a wire antenna several feet long, up in the air as best you can. I'd suggest ten feet minimum length, on up to maybe a hundred feet, but just do what you can. You can connect the circuit common to a "ground" made up of a ground rod driven into the earth, or just a wire on or close to the earth. Experiment! You're not likely to hurt anything, so long as you keep it away from power lines.

Dunno for sure about the background whine. Is it independent of tuning, or is it only there when listening to the station? Does the pitch change with changes in the tuning? Can you describe it better? It could be an oscillation in your circuit. Substituting the 12k for 10k should not be a problem. But I'd add a bypass capacitor across the battery voltage (and keep all the leads reasonably short) I'd use maybe 10uF at 16V or more, be sure the polarity matches the battery, and put it physically near Q3.

In troubleshooting things like the whine when you have limited test equipment, you can just try things like opening connections in the circuit to see which part of the circuit it's in. For example, disconnecting the 100n capacitor should tell you if it's a problem in the input section or output.

Good luck, and don't be afraid to experiment.

Cheers,
Tom

3127. How can a wire wound reisitor be non-inductive?

By winding the wire so the inductance cancels out you get a noninductive
resistor. They are really noninductive at low frequencies. Once you get
above the audio range they become inductive. I doubt they would work for
your case.

Use a Motorola MC3357 or MC3359 IC for the FM rcvr section...you can easily put in in the 1st IF of the CB and get FM detection as well as noise squelch (while the AM CB uses level or S meter squelch)..I do have a HyGain 16 on 10FM with a true FM scanner IF in it ...worked great.

Either there are two stacked windings, wound with opposite rotations,
or the winding is a zig zag, one turn one way, followed by one turn
the other way.

There used to be great big resistors -- essentially carbon composition
-- that were truely noninductive. I suspect they're still available.
My 1988 handbook has a UHF dummy load design that features a Carborundum
part number 889SP500K. With coolant it's good for more than 1500 watts,
so it may be oversized for you...

You can still find the occasional 2W or 5W carbon comp resistor -- if
you're working at HF you can easily parallel these to get the resistance
that you need.

Thanks Ralph, that is what I was thinking but when they are advertised as non-inductive you would think "non-inductive" wouldn't you. I guess I'll have to dig around in some old junk boxes or parallel several 1 watters to get them to work.
I appreciate your information.

Crazy idea but I'll throw it out here anyway.

We know that carbon film resistors have some worriable inductance at 6 meters. If a guy were to take a group of say 1-watters to make up the power rating, could you count on the consistency of the outer markings to the extent that you could group them somehow in parallel/inverted so that they cancel each other's inductance in this application?

Check out the Caddock and Vishay noninductive metal-foil resistors.
As I understand it they use a serpentine-path foil pattern, which
cancels out the inductance quite nicely. Some of them are advertised
as having an inductance equivalent to an equal-length piece of wire.

They're available in packages such as TO-220, and can be attached
directly to a heatsink (no insulator required).

I just figured the power rating on the three resistors I need and it looks like I may have some 2 watt resistors in the junk box that are carbon that will work. I'm trying to pad the input to an amp that needs 5 watts drive and my rig puts out 10 watts. It appears except for one resistor (the series resistor) 2 watt resistors will work fine. I can parallel X2 of the value of the series resistor and get the power rating I need. Thanks for all your help. I've been out of this stuff so long that I have brain fade occasionally.

Look up for bifilar winding.

If your exciter is reasonably clean so that you do not think about
proper termination also for the harmonics, you just need an attenuator
for a single frequency, which should simplify things a bit.

Even if a "non-inductive" resistor has some inductance at 50 MHz, it
should not be too hard to compensate for the inductance and turn the
system into a very lossy series resonant circuit, in which the
impedance is dominated by the resistance in the area around the
resonance. An other alternative would be to put a capacitor in
parallel with the resistor to form a parallel resonant circuit at 50
MHz and the actual resistance would heavily damp the resonance. If the
inductance is sufficiently low, you will end up with capacitances that
are practical (i.e. not affected too much by stray capacitances).

This kind of approach should work at a single frequency(band), but if
multiple bands are needed or if the harmonics also needs to be
correctly matched, this approach does not work.

I found a graph that I copied off the web sometime back showing the reactance of various R vs freq for metal film resistors. The 10-1000 ohm range of resistors show as being dead flat at 50 MHz compared to DC...and well beyond. Above and below values tend to go nuts with frequency, the high >100k values in particular.

I don't remember where I found this graph but based on it I'd think you have a good chance of making those particular values work using garden variety ten-cent 1-watt resistors...thinking along the lines that manufacturing of plain old carbon film resistors would follow the same trend.

I think its worth a try.

Thanks for the further information. However, here is my problem: first,
for me its a long drive one way (5-6 hours and I'd have to stay in a
motel Sat night, come back home Sunday, PM). Then, I was driving around
yesterday and the bigger problem: sticker shock at the gas pump
(I was gazing at a sign that showed $2.30+/gal for low test regular) . I'd
be spending more money on gas for the round trip than I'd expect to spend on
goodies, toys, parts, etc at the fest itself. :-(

Wind up approx 40' of RG-174 into a small coil and tie wrap it. It will
handle 100W + at 50 MHz and have a great return loss.
Lots easier than fooling around with resistors of questionable
characteristics and heating problems.

Use a length of lossy coax for only 3 db. A lot cheaper. None of the non-inductive wirewound or laser cut resistors will be truly non-inductive at those frequencies. Realize that the values need not be exact, because return loss will keep the SWR down. If you can't get Carbon, Use the coax. You might also want to adjust Drive or ALC in the amp.

The Collins 30L-1 used to come with a length of lossy coax for this reason.

Now there is a great idea and I have a 100' roll of RG-174 in the closet. Sounds like a winner. It's a shame that we can't get parts like were available 30 years ago. I'd like to build some old design tube receivers and transmitters. I was born in 46 and just got a 1946 ARRL handbook off Ebay with a lot of things that look interesting.

Thanks to everyone for their input on this matter.... and not one flame in all of the answers, that's rare on the user groups anymore!

I understand completely, Art. I'm in the same boat when it comes to distant hamfests. I have to run premium in my jeep and it's running $2.50 now.

Thanks anyway for you interest.

At 50MHz, you should find that metal-oxide resistors will work fine.
You're just making a power-wasting pad, not a precision attenuator.
(Carbon comps wouldn't be appropriate for precision work, either...)
The low-value metal-oxides I've tested on RF component analyzers have
all been fine for non-precision applications out to 150MHz. Try, for
example, Vishay FP69 series 2W parts or TT/IRC GS-3 series.

A couple years ago, I went through my stock of carbon composition
resistors and found more than half of them to be out of tolerance at
DC. They don't age well at all, even while not dissipating power.

1/8-W SMT resistors are so cheap that you could just use
series-parallel combinations of them to get what you need, too. For
more serious power dissipation, Caddock (and some others) have power
film resistors in TO-220-like packages which are low enough inductance
to be quite useful up into VHF and maybe above.

Cheers,
Tom

The other half of them would probably be out of tolerance too, after having been soldered.

I just came across an attempt to use carbon comp resistors (obtained with some difficulty) as RF impedance "standards" - completely hopeless. Small wire-ended metal film resistors would have been just fine, because they don't change value significantly when soldered.

Wire-ended metal film resistors can be quite good for RF, but the parasitic inductance can vary. They are made by cutting a spiral track into a basic resistive tube, and the pitch of the spiral is changed to produce a range of resistor values. When the spiral becomes too fine, the process steps up to a higher-resistance 'blank' and the whole cycle starts again with about a one-turn spiral.

Thus the number of spiral turns can vary between about 1 and maybe 10. You have to scrape the paint off to see. The inductance can then be estimated using the standard formula based on diameter, number of turns and length, and it varies from a few nH up to maybe 100nH.

The problem is that different manufacturers make the steps at different resistance values, so resistors of the same DC value may have very different values of parasitic inductance. If parasitic inductance is critical, circuits that worked perfectly well with one make of resistor may have problems with a different make (as Elecraft recently discovered).

Yes, easily. The only problem with the TO220 packages is the shunt capacitance to the grounded tab - and the power dissipation is very low if the tab is not grounded.

3147. SP-600 Transmitter project

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-11 22:06:13 UTC
From: GBrown <gkbrown@gwi.net>
Message-ID: <tbudndlEEerLcE_fRVn-hw@gwi.net>
Source record: 18330

I just got done restoring an SP-600JX-1. I am now looking for an SP-600 front panel, side supports and the two window escutcheons. The reason being..... I am going to reverse the panel and build an AM transmitter using the reverse panel as the front panel to the home brew transmitter. Thinking about a single 813 with maybe some 6146's as modulator. I don't care what the condition of the panel is. I would also like to find some SP-600 knobs. I am going to use a VFO from a junker HT-37 and just run 75 and 40 meter AM/CW. I think this is going to be a fun project. Any one have a suggestion as to a model number for this homebrew xmtr? Something along the line that will go good with "SP-600"

Well, thanks again.

FWIW, it sure would be nice if for some of these fests
someone could go around, at the end, with a video camera or d-cam and take
pictures (something like for that URL of the last one) of the unsold major
stuff (and maybe guys selling parts?) and post these on the club website
as a "possibly still available" item and an email address (or something
like that).

All a guy would need is: a cardstock with price and email address in felt
tip pen ink, held in front of the gear. That shouldn't be too hard, or the
guy selling the stuff could provide his own jpeg images on a floppy disk.

I'm not particularly interested in eBay/auctionering stuff
(since you have to play the escalating price game, then the shipping
question, etc). But, if a guy said "Here is X, I'd like Y dollars for it,
and subject to negotiations" I could get more interested in this.

Art, W4PON

I just found an old Narda 3db pad in my junk box. It checks good and is rated at 5 watts. Since I am concerned with SSB only, I can cut the carrier back on CW, I think the Narda will work with the SSB signal since it won't be continuous duty and the pad is rated at 5 watts continuous. I'll give it a try... I don't even remember having this thing!

I've seen several books that detail the electronic how to when it comes to building an HF RF amplifier from 100 watts to 2 KW. Great! They also show the amps sitting in these finely crafted metal cabinets. Ok well.... I don't know how to build a nice metal cabinet, and the books don't tell me. So....Now that I've decided I really want to build one of those nice home brew amps I need to know how to make the metal cabinet to put all those electronic parts in. Is there a book or web page that teaches how to build a nice metal cabinet to put those homebrew amplifiers in?

Curious George

In the traditional world, the chassis and enclosure are related but separate items. The common technique is:

1. Electronics built on aluminum chassis box. Available pre-fabricated from Hammond etc. Or make your own from sheet metal.

2. Front panel bolted to the chassis box. Knobs and switches and meters go on the front panel. And are either wired to the stuff inside the chassis or control variable caps etc. on the chassis via long shafts. Front panel for a big project is often 19" wide rack-mount panel (again a standard size available from Hammond et al.)

3. Enclosure is a sheet metal box that slides on from behind. Made using sheet metal tools.

At the high end, "sheet metal tools" are a big shear for cutting and a brake for bending. At the low end you make you own brake out of 2x4's and hinges, and cut with hacksaw/table saw/aircraft snips (depending on type of cut, thickness, and material.)

For the really classy look all the holes you need can be cut with punches. More likely for a hobbyist is drills and hacksaws and files and the most valuable tool of all: the nibbler.

Tim.

I had a couple of questions regarding recievers that I haven't been able to figure out. I'd appreciate it if anyone could give me some insight...

How well-defined is the gain for a cap-coil loop, like in an AM radio? (i.e., how fast does the gain droppoff as you move up or down from the 'tuned' frequency?) Is it a function of L and C? Or just frequency? (different combinations of L and C will tune to the same frequency, but is the gain the same?)

How come the coils on many of the CR schematics I've seen have multiple tap locations? It seems that with a variable cap, you should be able to tune to whatever frequency that's in your range. Is it to increase the range of your radio's coverage? Or because the gain at certain frequencies is better with different C/L combinations?

Thanks in advance for any insight!
Dave

Tom,
Thanks again for the advice. I originally attached a 10ft wire
directly to the L-C loop, and that helped a lot. But I've read
somewhere that it's best to magnetically couple it instead of directly
attach. Why is that?

I figured out the background noise... I had a TV, 3 lights, and a fan
motor going within about 15 ft of me. The background noise dropped off
a lot once I cut them off.

Dave

And if there's a good sheet metal shop in your area (there is in mine), you
may be able to get the owner to custom-make stuff for you for prices that
merely make you want to scream. But that way you'll get what you want, or
at least what you told the owner you wanted.

My preference, when I get to indulge it, is for rackmount panels with one
or more chassis boxes bolted to it, and subchassis inside those as seems
appropriate.

For the L-C resonator itself, the falloff will be 6dB per octave (doubling of frequency) once you're well outside of the center (tuned) frequency. The 3dB bandwidth will be determined by the Q of the circuit, and this is often not particularly well defined during the design stage -- often a well-defined bandpass filter somewhere "down the line" (e.g., at an IF stage) will ultimately define what the radio receives.

The 6dB/octave drop comes from just looking at the impedance or transfer function of an LC(R) resonator -- you'll end up with an s^2 (frequency squared) term in the denominator of the equation.

> (different combinations of L and C will tune to the same frequency, but
> is the gain the same?)

No, although for low Q resonators, it's often pretty close.

> frequencies is better with different C/L combinations?

They're usually trying to match the impedance of the LC circuit to the input impedance of "the next stage" (i.e., a transistor amplifier) to maximize power transfer. So, while it's not really "gain" (we haven't amplified anything yet -- this is more like a resistive divider), the output will be higher with different C/L combinations.

Generally speaking, most relatively simple AM receivers are really only intended to pick up relatively strong, nearby transmitters. As such, you can get away with an awful lot of "cut and try" when it comes to designing the circuit (largely ignore matching impedances, Q's, etc.) and still obtain acceptable results.

Hi Dave,

Well, you can couple the signal from the antenna into the radio in different ways, and though multiple ways may work, one may be more practical than another, and may be more efficient with available parts. The feedpoint of an antenna--the place you couple signals in or out--may look like a low impedance or a high impedance; it may have quite a bit of reactance in it (what look like capacitance or inductance). Getting the most signal out depends on matching to that impedance. Fortunately, for most medium-wave signals (standard broadcast), you can have inefficient coupling and still have a very useable signal, because the signals have to be pretty strong to be useable. They have to be larger than the atmospheric noise, which is rather high at those frequencies.

A disadvantage of simply connecting an antenna wire to the "hot" side of the LC at the receiver input is that a random wire will likely have quite a bit of effective capacitance, causing the LC to be detuned from what you expect. And if the wire is fairly long, it may represent a relatively low resistance, which will make the tuning much less sharp--it will lower the LC (tank circuit) Q--and you'll be listening to more than one signal at a time with your simple receiver design.

It can be an advantage to make the coupling variable. You can do that by changing the number of turns, or by moving the ferrite rod into or out of those turns, with the inductive coupling. Or you can connect the wire to the "hot" side of the LC tuning tank through a small "trimmer" capacitor.

There's a lot more to the story, which you'll learn by studying, experimenting, and keeping an open mind and high level of curiosity about things. Joel in your other thread told you some about bandwidth of LC tanks...you can determine the Q by measuring the 3dB bandwidth of the tank. Then the Q is center frequency divided by bandwidth. If you have a good coil and capacitor, and no circuit loading the LC, the Q might be, say, 200, limited by losses in the coil and capacitor themselves. If you add a resistor--either a part designed to be a resistor or a circuit that has an effective resistance--it will lower the Q and broaden the bandwidth. If the power lost in the resistor is equal to the power lost in the coil and capacitor, you will have a Q that's half as large--100 in this case. A receiver designer will pick a Q that doesn't limit the bandwidth too much, but gets rid of interfering signals. And if the receiver relies on two or more LC tanks to track together, the Q will be picked a bit lower to allow

errors in tracking without hurting the performance.

Again...this is only scratching the surface. You should probably look for some books like "Radio Amateur's Handbook" for a lot more discussion of things like tuned circuits.

Cheers,
Tom

CG -

Chris, G3WOS has a nice story with extensive photos of building a 50 MHz
DXpedition amplifier using the Eimac 8877.
http://www.gare.co.uk/amplifier/

He built an actual cardboard mock-up of the amplifier case
http://www.gare.co.uk/amplifier/dxpedition_amplifier_mock_up.htm

created a set of cabinet plans (Adobe Acrobat) from that mock-up
http://www.gare.co.uk/amplifier/DXpedition%20Amplifier%20case%20design.pdf

then had a metal fabrication shop to build the actual cabinet.
http://www.gare.co.uk/amplifier/dxpedition_amplifier_case_design.htm

Chris also used the G3SEK Triode board !
http://www.ifwtech.co.uk/g3sek/boards/triode/triode-1.htm

Source record: 18347

I have an external RF transistor amplifier (AB1) using 2 MRF455 transistors in common emitter mode. I have a resistive T pad with an approximate impedance of 50 ohms on the input side of the transistors. The SWR on the input of the amp shows 1.3:1. When I use a 2 foot jumper between the radio and the amp the amp puts out about 100 watts max, but when I switch to a 9 foot jumper the amp puts out about 40 watts max. The receive stays the same no matter which jumper is used. Why does changing the length of the jumper between the radio and the amp make such a drastic change in how much the amp puts out?

Are you sure the 9 foot jumper is good?

What frequency is this occurring at?

Is the SWR 1.3:1 for both jumpers? Measure the SWR, forward power, and reflected power levels at the transmitter end for both jumpers and then measure it at the amplifier end for both jumpers. See if everything stays the same for both jumpers.

Do you have an RF probe you can use to measure the voltages at each end of the link?

Unless you are using rg174 the 7 foot of extra cable should not make this much difference unless the input impedance of the amplifer is not 50ohm resistive. If it is not purely resistive then changing the cable length can impact the SWR seen at the transmitter end significantly. This could cause foldback in the RF amplifier in the transmitter thus affecting the output of the amplifier. This would all be seen in the measurements of SWR, forward power, and reflected power levels in the measurements above.

Let us know what you find.

Changing the cable length won't change the SWR on the cable regardless of the kind of load impedance and, if the SWR meter is designed for the cable's Z0, it won't change the SWR meter reading, either. Except, of course, that cable loss will always lower the SWR -- but that shouldn't be a significant factor with such short cables.

Changing the cable length *will* change the impedance looking into the cable, whether or not the load is purely resistive. The only exception to this is if the load is resistive *and equal to the line's characteristic impedance* in which case the impedance looking in will be Z0 for any length cable.

Transmitters will often put up with some mismatched impedances better than others, even if the SWR is the same, and sometimes changing the cable length between it and a mismatched load will cause it to see a more or less favorable impedance. But if the SWR really is 1.3:1, I doubt that's the cause of this problem.

I agree with the suggestion that the OP measure the SWR and if possible the power at both ends with both cables. Something else is going on, like maybe a bad cable or connector.

I don't think the OP said what frequency this is happening at. That might give some additional clues.

I am assuming this is VHF and if so I would say that there is a bad connector at both ends - PL259s. These are not good enough connenctors for use anywhere above HF, the are simply screened banana plugs. If this is a ready made jumper for the CB market, the cable might not be anything like 50 ohms.

3171. Frequency multipliers: Usable modulation formats?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-13 15:13:06 UTC
From: Joel Kolstad <JKolstad71HatesSpam@yahoo.com>
Message-ID: <11dabp5hfvvv25@corp.supernews.com>
Source record: 18211

I was over on comp.dsp exposing my ignorance the other day when it eventually dawned on me that a frequency multiplier will, in the frequency domain, just convolve whatever the input signal is with itself. This got me to thinking... why is it that frequency multipliers work as well as they do for something like FM? Assuming a sine wave modulating signal, the FM spectra is a sum harmonics with amplitudes dictated by a Bessel function; frequency multiplying this would seem to add new harmonic content to the mix besides just doubling the frequency of what's already present. So... does it turn out, mathematically, that frequency multiplying an FM signal just so happens to end up what nothing more than a "frequency scaled" spectra of what was originally present? Or is some amount of distortion added in the process (assuming perfect mixers used as the frequency multipliers and the DC component of the mixers' outputs removed).

I've been told that, in general, frequency multiplier can be effectively applied to most any modulation scheme that has a reasonably constant envelope, e.g., FM, PM, FSK, even QPSK. Is this generally accepted knowledge?

Thanks,
---Joel Kolstad

Suppose a 1 MHz signal is frequency modulated by a 1 kHz sine wave. The frequency deviates over some frequency range, for example +/- 5 kHz. If we put that signal into a times-ten multiplier the FM signal is at 10 MHz and the frequency deviatioon is ten times greater (+/- 50 kHz). However, the *rate* at which the 10 MHz signal traverses the greater frequency deviation is still 1 kHz. That does not change and that is what the FM detector output delivers.

The "best book" is simply COMMON SENSE. Use your eyes and brain.

If the voltage and current through your body in the path of the
heart is above 30 Volts and greater than 30 mA, you have the
approximate threashold of cardiac fibrillation...where the
heart loses its normal oscillation and begins to "flutter"
and not pump blood. Potentially fatal if this "30-30" rule
is exceeded.

DON'T GRAB LIVE HIGH VOLTAGES WITH BOTH HANDS. [guess where
the heart is located in this body "circuit"?]

A common mistake of the above is leaning on a conductive surface
touching it somehow when probing with the other hand...the
"circuit" has been completed even though it may not enter
awareness.

Be AWARE of the maximum voltage limitations on all your measuring
equipment. If a manufacturer says "input voltage 500 V max"
that IS what they mean...there's a "fudge factor" in that rating
but try NOT to use it. Do not destruct expensive test machines
or the circuit you're testing.

THINK about what you are doing around high voltage. Thinking
will enable you to continue living to think some more about
other things.

RESPECT high voltage. It ain't no kiddie toy to fool with.

LenAnderson@ieee.org

[a high voltage survivor in the biz since 1948]

Good suggestions on simple checking of a cable AND connectors.

The six-decade-old design of the PL-259 is not the best on "wiping" action of contacts on the sleeve (outer conductor portion). It is a license-free standard design, standard because it is relatively cheap. Cheap silver plating can corrode fairly easily (rhodium flash over silver plating is much better but costs more)

Yesterday my "ancient" HP-722 inkjet printer had no primary power. Check of the AC cord, external supply, said that was okay. Turns out that the coaxial connection to the back of the printer had developed some kind of minor corrosion. Simple unplugging and re-plugging that DC connector brought back primary power.

Three decades ago I was involved in a seemingly "unsolveable" problem in Navy-flown L-Band R&D system. Signals would just cut out at altitude, said altitude varying depending on day of flight test. System AND RF cables (to top and bottom fuselage antennas) all checked out fine on the ground. Nothing intermittent. Blade antennas were taken off and checked okay, put back. All type N connectors, good ones. Trouble was in an unlikely form of a "doubler plate."

"Doubler plates" are often used in retro-fitting antennas and other things on aircraft, just a sheet of metal to re-enforce strength of the metal skin. The doubler plate drawings had clearance holes just too close to type N connector sleeve outer diameter. Connectors mated, but NOT fully. As altitude

increases, temperature drops. The not-fully mated center conductor pin just contracted until it lost contact at cold temps. Enlarging the doubler plate clearance hole allowed full mating, no shrinkage of contacts. Unlikely problem solved at about quarter to 8 PM in a cold hangar. :-(

Sometimes the "unlikely" not-described-in-text things are to blame.

I was in Anchorage when color TV was first being broadcast there (mid-'60s) and people were using outside antennas with coax feed for the first time. The center pin of a male type F connector is just the center conductor of the RG-59 cable, and on a cold day the center conductor would shrink enough on a long cable run to pull the pin out of the female connector.

Anybody who has spent some time as a technician (as I did) has a long list of tales to tell about strange problems. Among my favorites are a car with the battery installed backward (a Corvair -- car started and ran, but gauges were funky and the radio blew), and a piece of copper pipe with 300 ohms DC resistance. But those are just a couple. . .

3177. QUESTION: Fun with Svetlanas or Staying alive with kV power supplies

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-13 21:05:17 UTC
From: Timothy@tholtom.freeserve.co.uk
Message-ID: <1121288717.540109.24910@g14g2000cwa.googlegroups.com>
Source record: 18209

My knowledge of vacuum tubes and kV power supplies is limited. I have
been reading an article in the ARRL Handbook detailing the construction
of a 1kW HF Linear. I'd like to try my hand at building something like
this. I found the article a little intimidating: Ceramic insulators,
parasitic suppressors, thermal and mechanical engineering etc. Is
there some book that details this type of thing with an explanation of
the whys as well as the whats and hows. My priorities are:

1) Safety. I'd like to be alive to make my first 1kW QSO
2) Avoiding equipment destruction, arc overs, black smoke, explosions
etc
3) Safetly troubleshooting this kind of equipment, loading testing
etc.
4) How to deal with tubes: warm up, care, etc...
5) Avoiding TVI (ITV), parasitic oscillations etc.
6) Longevity and Duty Cycle issues etc.
7) Costs and sources.

Hope someone can help.

Thanks,

Tim

3178. QUESTION: Spectrally pure DDS Output?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-13 21:18:40 UTC
From: Timothy@tholtom.freeserve.co.uk
Message-ID: <1121289520.683685.321330@o13g2000cwo.googlegroups.com>
Source record: 18210

I have the following question regarding DDS chips:

The amqrp website and others detail techniques for using Analog Devices', DDS chip as an accurate digitally controller oscillator. One of the issues that needs to be bourne in mind according to the articles is the spectral purity of this chip's output. There seem to be various schemes using PLL and filtering to kill the harmonics and spectral "grass" that these things seem to generate. Given the onward march of technology, is there any chip similar to the Analog Devices DDS, that would give be a spectrally pure, low noise sinusoid with any further filtering or PLL? I'd like something good enough to be a high quality VFO for an HF receiver (I and Q available)?? Is such a thing available, preferably offering a presoldered evaluation board (I don't want to go blind soldering it!!) for 30 or 40 bucks kind of price range??

Thanks,

Tim

Does anyone know of a cheap and accurate shaft encoder assembly,
suitable for that "professional rig feel" for spindle position to
frequency encoding. I'm thinking about some sort of integrated unit
that contains the encoder, code wheel, assembly, bearings etc.

Can anyone help....

Tim

HP used to make very nice optical rotary encoders - e.g. the HEDS-7500
"digital potentiometer" (which has its own shaft and mounting), and
the HEDS-5000 series optical encoders (which mount on an existing
shaft). These are from a 1989 catalog, and the current versions or
equivalents are no doubt different. www.newark.com lists a bunch of
them.

I would not call them "cheap".

According to Digikey's catalog, Grayhill and Clarostat and Iwatsu and
Bourns all make similar rotary optical encoders with reasonably high
pulse-per-revolution counts (128 or 256).

It looks to me as if you're probably facing a price of $40 - $60 per
piece, in single quantities, for any commercially-made rotary encoder
of this caliber.

For anything very much less expensive, you'll probably have to
homebrew something (e.g. a couple of simple interruption-type
photosensors, and a code wheel laserprinted on a piece of plastic) and
mount it on an existing spindle/shaft.

===>
If this is a 2m transmission system 2ft of coax equals 610 mm. Assuming a coax velocity factor of 0.67 ,the electrical length is 1/ 0.67 * 610 equals 915mm which is about 'half a wavelength'.
Half a wave lenght of transmission line is an 'impedance repeater'
Hence if tx output- and amplifier input impedance are about the same ,there is max power transfer.

Nine feet of coax for the above does NOT equal a multiple of half wavelenghts hence the reduced power input to the amplifier and subsequent lower amplifier output.

Just try to reduce the nine feet coax cable to about 8 ft which would be about 4 half wavelengths . The result should be an amplifier output > 40 Watts

You can readily make multiples of (electrical)half wavelength by using an MFJ259B antenna analyer or even better a spectrum analyser..

An electrical half wave (or multiple half waves) 'shorted' stub has a LOW impedance at the other end .

Take a piece of coax which is slightly longer than a multiple of (electrical) half wavelengths.
Fit a suitable connector at one end and connect to impedance measuring instrument . Now penetrate the coax with a needle at the other end , observe the impedance.
The needle shorts the coax centre conductor with the braid.
Change frequency up or down finding the nearest freq where impedance is minimal .
By penetrating the coax nearer the connected end you can find the length where the impedance is minimal at the desired freq. That length is a multiple of elctrical half wavelengths , and hence the optimal length of your lead.

If you don't like the 'needle operation' , you can make an electrical quarter wave '0pen' stub .

Again you start with a length of coax slightly longer , check the freq for which the stub shows minimal impedance and subsequently cut tiny bits off the stub until the instrument shows minimal impedance at the desired freq.

The lead you need between transceiver and amplifier is to be an EVEN multiple of the remaining length of coax

I have done the above to optimise power transfer between a vintage Yaesu FT290 ,2m transceiver (2.5W) and a 30 Watts power amplifier.

Note : The characteristics of open-ended and shorted transmission line sections is well described in the ARRL Extra Class License Manual (my copy is from 1990)

When I was a kid, I was building 10kV HV transformers, 100kV Tesla coils, spark coils, discharging HV capacitors that make "bangs" about as loud as medium sized firecrackers, smoked resistors, shorting outputs on 100 amp transformers just to see the sparks fly, etc., and so I have an intuitive feeling for various stuff. I've gotten shocks maybe a dozen or two times in my life. Nasty. Most of the time these were from a finger to thumb and not through my heart. When current was involved, I'd get a button of burned flesh on my skin and that really hurts plus burnt flesh really stinks like almost nothing else except dead flesh that has been dead long enough at room temperatures to really stink. RF burns...you don't feel the pain (which also really hurts) until after the burn and you get that burnt flesh stink, too. Even from 50 watt rigs they can be bad.

My experience includes mechanical devices, electric drills, bolts and nuts, threaders, chassis punches, electric drills, band saws for cutting metal sheets, etc.

If you have never done anything "hands on" in your life, then your grand plan dream may be an undertaking that you would be wise to avoid. On the other hand, if you are mechanically inclined and practical and NOT a klutz (definitely not a klutz), then I'd suggest starting with a smaller and easier project and then move up.

At points where you start working with lethal voltages and currents, you do need to be careful. Very very careful. They say when the power is on and the cabinet is open, you need to keep one hand in one of your pockets. Stand on a piece of dry wood at least 1/2" thick, etc. Yes, arcs and smoke can be intimidating. Just the surprise from an arc can make you jump in an unpredictable way and if not hurt yourself from the electrical shock, then you'll bang your head or something else.

Parasitic oscillations and TVI: At least start with a KW level dummy load and know what the book says about neutralization and how to test for it and adjust it. Also, you cannot have enough meters to measure everything. Even filament voltage and current. I'd have a meter for every circuit: plate, screen grid, control grid, cathode current, and voltages on all of them.

Weirdest discoveries: serious RF noise from solid-state diodes. Also, serious RF noise from HV transformers (output connected to absolutely nothing, but AC on primary and can hear the noise across the SW band). Weirdest lightning effect: blew out a very big (1 kW) plate transformer (2200-0-2200 v) and bypass capacitors to ground and nothing else in the hamshack was affected (collins S line, Drake twins, ten tec rig, etc.).

Key warning: know what you can and can't get away with using HV silicon diodes.

Building your own gear: I have had no sense of pride, accomplishment, and usefulness like building my own. Especially from junk in the junk box. My biggest rigs were 500 watt linears using 4-400As, and a few others. Built kits (Knight, Heath [too bad they are not around any more]), too.

There was an article in "Radio Electronics" (or maybe it had morphed
into "Electronics Now" by that point), I'd say around 1994 or
so. The concept isn't much more than taking the outputs of the stepper
and putting them through comparators to get a binary waveform. But of course,
picking the right stepper is important since you need the fine steps, and I
know when I brought this up before, someone had something to say against
the concept, though I sure can't remember what they felt was wrong
with the concept.

I built a homebrew KW about 15 years ago using a pair of 4-400 in
grounded grid. It worked fine on 80-20 but I never did get the tank
Q adjusted well enough for good output above that. Not that it couldn't
have been done with a bit more tinkering.

The power supply put out about 4000 volts no load. I used a time delay
circuit with a relay and a power resistor to limit the in-rush current
while the capacitor filter bank charged. It had a relay whose ac coil
was across the primary of the plate transformer that shorted out a power
resistor in series with the primary. As the caps charged and the input
current fell so did the voltage drop across the power resistor until the
primary voltage rose to the relay's pull in voltage shorting out the
resistor. (Idea from ARRL HB).

A second time delay circuit did the same thing for the filaments of the
4-400's. This relay also locked out a second relay that applied power
to the plate transformer. Result, the plate supply couldn't be turned
on until the 4-400 filaments were warm, that delay was about 1-2 seconds
during which a power resistor in the filament transformer primary
limited the 4-400 filaments to half voltage.

The filter caps were 10 330uf 450v computer grade units in series, each cap bridged by a 50k 25W power resistor to even the voltage across the caps and act as a bleeder resistor. A 1ma meter with a suitable multiplier resistor in series served as a voltmeter across the capacitors (I forget how many meg ohm it was). The meter case was thick enough plastic to be insulated enough from the chassis (and and besides the main plumbing was behind several meg ohms). The meter read 5000v full scale.

I always assumed there was voltage across the caps when I worked on the rig. First pull the plug(s). Wait till the voltmeter drops to zero. THEN put a heavy screwdriver with a well insulated handle from ground to the HV terminal to be sure! (I used to do that to picture tubes when working on tv sets). Keep on hand in the pocket if you need to adjust anything when it's hot. BTW an RF burn can be more deadly than a DC jolt. (Think microwave oven).

HV isn't the only thing that can get you. High current can give you a nasty surprise. Like the guy replacing some batteries on a golf cart. He was using a ratchet wrench to tighten the battery clamps and he ended on the most positive battery terminal. The handle of the wrench hit the chassis of the golf cart putting it between 36 volts and ground of some VERY HEAVY DUTY batteries. Ever see a Sears ratchet wrench glow WHITE HOT? (and melt?)

No distortion per se, but, in multiplying the carrier by an
integer number, you also multiply the deviation by that same
number. You do the math, I did that a long, long time ago. :-)

>I've been told that, in general, frequency multiplier can be effectively
>applied to most any modulation scheme that has a reasonably constant envelope,
>e.g., FM, PM, FSK, even QPSK. Is this generally accepted knowledge?

It has been accepted - and done - since at least 1939 for
FM and PM.

The first dedicated radio relay sets for the U.S. military,
using Type C Carrier equipment in/out (four voice channels
frequency-multiplexed within 12 KHz bandwidth), did that
with crystal control, a reactance modulator, and lots of
multiplication to reach VHF. See AN/TRC-1, -3, -4 70-90
MHz sets. Long-lived sturdy-bird radios they were.

Had there been distortion in the multiplying process, the
Carrier equipment it worked with wouldn't have functioned
properly. However, it worked just dandy. :-)

Most of the early FM radio transmitters were of the crystal
oscillator into a reactance modulator and then into Class
C frequency multipliers...broadcasting to police car
radios. About the only way to get FM or PM in the very
early days was by a reactance modulator. In the post-war
period there were some specialized tubes made for FM/PM
modulation but those are collector's pieces now. Took lots
more years before the variable-capacitance diodes appeared

to mess with an oscillator's tank for FM.

See "Carson's Rule" and things of that nature in a search.

A DDS chip on its own may cost more than 30...40 dollars, unless the manufacturer is willing to send you a sample. And what is wrong with AD 995X series DDS? They are of a very low "spectral grass". You can also get an idea for how much AD sells their DDS evaluation boards by browsing their product catalog.

I am reading through the excellent book "Solid State Design" by Wes Hayward et al. I have a specific question on Class C amplifier. On chapter 2 Fig 15, a Clas C amplifier is shown with a buffer amplifier link coupled in front.

Why is link coupling needed here, can't the collector be directly connected to the base? It is for impedance matching or is there any other motives behind this structure?

In a previous life, I was reaching way to the back of a cabinet of radar equipment for some reason. I was lying on my stomach, my arm was extended all the way, and my head was into the cabinet doorway about at the forehead level, with a couple of inches clearance above and below. Of course all the safety precautions were followed -- some of the heavy ground radar stuff I worked on was easily lethal. But there was some charged capacitor, something hot from another cabinet of gear, I don't recall, and I got a minor shock. My instinctive reaction was to jerk my head up, and it hit the top of the doorway. That hurt and made me reflexively jerk my head downward, hitting the bottom of the doorway with my forehead. That caused a jerk back upward, hitting the top again, and so forth. There I was, oscillating up and down, beating my head to a pulp, knowing exactly what was happening but helpless to do anything about it. It continued for what seemed like a long time, until I was sore enough that I couldn't feel one more whack, when I was finally able to stop and extract my head and arm. I guess I've felt as stupid a few times since, but only a few times.

And when you bend your arm every which way in order to get at something, it might go in all twisted contorted, but it comes out fast and straight when you get bit. I've lost a bit of skin that way, too.

It's for impedance matching. As usual, there are several ways it can be done, each with its own advantages and disadvantages. That method is probably the simplest for the particular application, but you have to watch the flux density in the transformer primary if it's wound on a ferrite core with no air gap (such as a toroid core) and make sure the D.C. current won't cause core saturation. Other methods allow you to separate the RF choke from the transformer, like in Fig. 16, so you can optimize the RF choke for its job and the transformer for its job. Or you can use several types of LC network to do the job.

Steppers have no output unless the shaft is moving. Steppers used this
way are really a velocity encoder and not a position encoder.

Probably dumb (and WAY off topic) question:

What's the *intended* purpose of a 450v "computer grade" capacitor?

Yep. Great story. Reminds me about that sad/funny joke about the guy, his
tower, bucket of tools in a wooden barrel, ropes, pully, and somehow he
goes up and down the tower, wooden barrel breaks so the counterweight
disappears and he goes down again....broken bones, cracked skull, all
kinds of hospital damage. Funny/sad. Similar to the chainsaw joke. Anyone
remember or have those jokes stored away somewhere that they can drag them
out?

I didn't think I had any "funny" jokes like the tower joke, etc., but I definitely had some non-fatal "war stories" to tell. I also built a couple of those "repulsion coils" as a kid. Aluminum ring & coat hanger wire core & couple hundred turns of number 14 gauge wire, plug into AC line and the ring would shoot up 1-2 feet. Neat. Playing around with a high turns coil on it one day and didn't realize my fingers were on some terminals and I must have gotten a thousand volts pressed against my thumb: ergo, two burned spots on my thumb. And, that burnt flesh stench. Gawd did it stink. And, it hurt like hell.

Radar? I've heard a couple of stories of guys who walked in front of those dishes not knowing they were putting out KWs of microwaves and they got their tummy microwaved into cooked beef. Killed em dead. Better have a buddy around and you can ask him: "Hey, I think this thing is turned off...Am I thinking right? Please go look at all the switches and check, tubes lit up, fans running, hum from transformers, other noises? Please?"

That'd be http://monologues.co.uk/004/Bricklayers_Story.htm - at
least, that's the original one from Gerard Hoffnung - which dates back
a few years.

I used to play the tape of this as part of my 'Quality Awareness'
sessions - trying to make the point about forward planning, and
avoiding situations that are going to cause problems.....

There are further versions of this relating to towers and ham radio -
a google for Hoffnung + Bricklayer will turn them up

Probably funnier to read about than be involved with <g>

Take care

Roy,

Thanks a lot for the comments. I hope to homebrew some of those early
projects in SSD and then move to bigger projects elsewhere, as I have
not much of hands-on experience in building.

Thanks
Ramakrishnan

3204. What would cause the SWR to go up drastically when I turn my amp on?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-14 14:31:05 UTC
From: Joeseph <NOSPAM+++++@earthlink.net>

Source record: 18237
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment

This is a very screwy problem. First lets get the set-up of my
radio equipment;

The amp puts out about 100 watts on HF.

RADIO----->2 TRANSISTOR AMP----->SWR METER------> ANTENNA

Note the SWR meter comes AFTER the 2 transistor amp.

Ok, when I check the SWR on my antenna it shows 1.1. When I turn the
amp on it shows over 3.x SWR. The antenna is rated at 5 KW. The amp
only puts out about 100 watts.

Hmmm.....Ok lets see what happens when I use my 1 KW oil filled dummy
load.

RADIO-----> 2 TRANSISTOR AMP---->SWR METER------->1 KW DUMMY LOAD

Same thing. The SWR is about 1.5 in to the dummy load, but as soon as
I turn the amp on the SWR meter shows 3.x plus.

Ok, Maybe my SWR meter is screwy, so lets use my Dentron MT3000
tuner with a built in 200 watt dry dummy load and built in SWR meter.

RADIO ---->2 TRANSISTOR AMP---->DENTRON MT3000

Same thing. The SWR is low without the amp on and goes high when the
amp gets turned on.

Ok, Lets see what happens when I use my Drake L-4B amp instead of the
2 transistor amp.

RADIO----->Drake L-4B----->SWR METER------->Dummy load

Now the SWR stays low when I turn on the Drake L-4B for both the 1 KW
dummy load and the external antenna.

The transistor uses MRF455 transistors. Why would the SWR meter go up
significantly when I turn on the 2 transisor amp, but stay low when I
turn on a Drake L-4B.

I've duplicated this scenario with three different SWR meters, and
different patch cables. Lets me say for the record the SWR meter
comes after the amp, so I'm not looking at a high SWR on the input
side of the amp. This is on the output side of the amp.

?????

Thanks for the detailed reply, Len... I'll sit down and work through some of the math if/when I get a moment.

Could you tell which of the following is correct? -- Say I amplitude modulate my voice onto a carrier and feed it through a frequency multiplier. Besides shifting the carrier, does it just make me sound like a chipmunk (i.e., if I manage to hum a perfect 1kHz sine wave, the demodulated signal is me humming a 2kHz sine wave with a 2x mulitplier)? Or is there far more serious distortion present?

Check the frequency (or frequencies) coming out of the amplifier. I will bet
that what comes out is not equal to what goes in. The antenna is not a
good match for those other frequencies.

3207. MOV protection of 120vac circuits with high freq content

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-14 16:05:22 UTC
From: tjs <anon@anon.net>
Message-ID: <42d69178_1@news1.prserv.net>
Source record: 18240

Not a REC.Radio issue but still appropriate here...

Question: will 1-10khz harmonics riding along on 60 hz power cause protective MOVs to charge and short out thusly drawing damaging currents.

The scenario: I have an Allen Bradley PLC digital input card and it contains 1 MOV across ac input channel terminals (I think they are MDC Z181 spec). They are there to protect against high voltages at the terminals which I contend never occurs, never seen it happen. What does happens is that a 232 ohm 1/8th watt (current limiting?) resistor just ahead of the MOV will slowly heat up and burn to open circuit in about 30 seconds after connection. Using 0.125W (P=I^2 x R) 232 leads me to exceeding a current of ~25ma drawn to burn the resistor.

The IO being monitored is motor run status from a VFD driven motor (variable frequency drive, PWM type, naturally using ~50-100khz synthesis methods). The control power is riddled with harmonics from 500hz to 10khz, and I estimate 10vp-p maybe less (as seen on the oscilloscope). As soon as I close the electrical connector to the IO card the resistors start heating up, smoke, then fail.

I know I need to isolate the control power and rid the plc of the harmonics. I just want to confirm the high frequency components can cause MOVs to short as if there was a high voltage event when there isnt one. I beleive the capacitor model of a MOV means it should charge up at higher frequency, and maybe this is why it takes 30 seconds for smoke to appear.

Regards
Tim KF8XW

Virtually all multipliers we see work by overdriving a stage. This strips
off any amplitude modulation, so there's no modulation at the output of
the multiplier.

Well this isn't rec radio either!
A mov does not model as a "capacitor" it models as a (verY) non linear
resistor.

What is the continuous rating of the MOV.

Glenn:

I'm sure that limits stepper motors to certain uses, but I think this thread/post may be incorrectly titled. Unless I misunderstand the intended application, I don't think a "position encoder" is what he is looking for. Rather he wants something that, when rotated, feeds pulses to an up/down counter for frequency synthesis. The position of the shaft is not important as long as its rotation can be used to generate pulses for the counter.

Roger

What Bill is trying to tell you is that your amplifier is probably oscillating or putting out way bad harmonics. That certainly fits the symptoms with the antenna attached; it's a bit surprising with your dummy load unless the dummy load is only good to two meters (chances are your oscillation is higher than 2M, and harmonics certainly would be). You could also see odd results if the SWR meters aren't good beyond 2M, but I don't know which direction they tend to go with way high frequencies.

Any coupling circuit to a class C bipolar transistor amplifier not only needs to match impedance, it also needs to supply DC current to the base of the class C stage. Inductive coupling is nice because the average voltage at the base is nailed at zero and the inductor will guarantee that enough DC current flows. If you should capacitively couple then you need to load the base of the final stage with a back-biased diode or a resistor to provide the current -- otherwise your coupling capacitor will just charge up until no current flows into your final's base and you no longer get amplification.

Smart guy you are! I never thought of that, but it makes perfect
sense. I don't have a spectrum analyzer, but since the 2nd harmonic
and higher lands above 30 MHz then I should be able to place my Barker
and Williamson low pass filter (30 MHz cut off) between the amp and
the SWR meter. Hopefully the low pass filter will allow the
fundamental through, and stop the higher frequencies (assuming they
are normal multiples of the fundamental frequency). If the
attenuation is great enough the SWR meter should not show the SWR jump
since the unwanted frequencies should be attenuated before they get to
the SWR meter.
Assuming you are correct my next problem will stopping the extra
frequencies from getting out of the amp in the first place.

If the MOV voltage is well below its conduction threshold, then it
looks to the outside world, much like a small capacitor. So you can
expect that a signal with significant high frequency content will pass
more current through it than one with only line frequency content.

I don't recognize the part number of your MOV, but this data sheet for
some small MOVs lists the capacitance for a 132 volt AC unit is only
21 pF.
http://rocky.digikey.com/WebLib/Littelfuse/Web%20Data/MA%20Varistor%20Series.pdf

This bigger disc type lists the capacitance for the 130 VAC unit as
100 pF.
http://rocky.digikey.com/WebLib/Littelfuse/Web%20Data/ZA%20%20Varistor%20Series.pdf

If you can find a data sheet for your unit, the capacitance should be listed.

Your transistor amp is putting out garbage; transmitting harmonics that your
SWR Meter is responding to. You need tuning/lowpass filters on both input
and output.

Be sure to verify that it's not oscillating, and that any excessive
harmonics don't indicate some other problem with the amp (if you're in
the process of homebrewing it then it just means you forgot the dang
lowpass filter, but if the amp is a commercial unit & you're using it as
intended then there may be something broke).

No, your problem should be figuring out how to prevent them from getting generated in the first place. If the harmonic or spurious content is that high, there's something seriously wrong.

Roy Lewallen, W7EL

If I had to guess, I'd guess that your MRF455 amplifier may have some instability issues, and may have a nasty parasitic oscillation going on. You might also want to check its grounding, and the RF relay which I presume switches it into or out of the circuit. I'm guessing that you've got RF flowing where it shouldn't.

I picked up a few MRF455 transistors last year and have toyed with the idea of using them as a PA in a homebrew rig, but from what I can see in the application notes they require a goodly amount of care in the amplifier design and circuit layout. If they aren't used properly it looks to me as if they can be quite prone to misbehave, oscillate, etc.

If you can borrow a spectrum analyzer, take a careful look at the amp's output, and wave a probe around the amp itself (prior to the low-pass output filter). It would not surprise me if you find that you're spurring the horse a bit :-)

A trick, courtesy of Bob Pease: whenever you build a power supply
circuit which carries line voltage or higher, stick an NE-2 neon bulb
and a suitable dropping resistor across the caps, and place the bulb
where it's clearly visible when the case is opened.

If the bulb is lit (at all) the caps have enough voltage in them to
give you a nasty bite.

>THEN put a heavy screwdriver with a well insulated handle from ground
>to the HV terminal to be sure!

I've heard cautionary notes about this... if you do this prematurely,
the arc can be scary (and dangerous in some cases - "arc flash" burns
can be severe) and I believe it's possible to damage or wreck some
caps as a side effect of a catastrophic high-current discharge.

A heavy grounding wire, with alligator clips, and with a
current-limiting resistor is another possible solution. You want a
low enough impedance to drain away any charge which may come out of
the cap's dielectric "soakage", but high enough to avoid a dangerous
arc flash when you first hook it up.

> Keep on hand in the pocket if you need to
>adjust anything when it's hot.

That's one of the best single pieces of advice around! Also, be aware
of what sort of grounded metal is around your workbench. Doesn't help
much to keep one hand in your pocket, if you lean your belly against a
grounded metal bench!

Sorry , I crossposted to rec.radio.amateur.homebrew and sci.eng.electrical
sys-protection

I'm having trouble finding data on the MOVs. The markings MDC Z181 04UL seem
to point to a 175 vac 225vdc 17-19 joule device with 130 pf capacitance,
1200 amps Ipeak, 25mW transient dissipation. I searched Digikey and NTE. It
is about 10mm diameter disk type, maybe 8.5mm per some datasheets.

My brother came home from a business trip once with a scar on his wrist
5/8 inches wide and all the way around -- the truck was having
electrical problems & he shorted his metal watch band through the 12V
battery (there was a wrench involved in there somehow, of course).

I felt for him, but I was very glad that _he_ was the one to learn this
first hand, rather than me...

This is close the exact component I have.
http://www.maida.com/content/products/varistors/standard/fullRecord.asp?iACVolts=180&iDCVolts=0&iDiskSize=10&stylenum=D6121ZOV181RA04
It shows 320pF. Its marked 04UL is supposed to mean 40 joules, although the
data sheet says 60J.
Tim

I want to conclude that the MOV can short pulling over 25ma thru the 1/8th
watt resistor, heating it up, due to 10khz components on the voltage, and
not an actual high voltage. Would this be a true statement?

Thanks

The canonical "Take-Your-Rings-Off" reminder in our electronics shop
in Japan, back when I was in the AF, was a color image, taken at our
base hospital, of a finger burnt to the bone all the way around: one of
the techs had got his wedding ring between ground and a high-current
low-voltage supply.

My dad (the first W3DHJ) told me a similar story.

It was in the late 20's. He was working on _his_ dad's Ford utility truck. (Grandpa owned a dairy in Big Bear, Calif.) Six volts here. The truck was parked in the driveway -- just outside the garage. When my dad caught his ring between the positive terminal and the truck frame, my Grandpa picked him up bodily -- ran him over to the rain barrel at the corner of the garage -- and stuffed my dad's entire left arm (and much of his upper torso) into the barrel.

(*The worst* thing you could do in a situation like that is try to _pull_ the ring off.)

My dad was a 90-day wonder in WW II. He then spent 25+ years in the U.S. Army Corps of Engineers (we traveled the planet....) Most of his duty assignments were as Post Engineer -- with the added responsibity as Post Safety Officer. I always knew him to be evangelically anal about safety. I'm sure that incident with the old Ford truck had a wee bit to do with it.

Without having the exact waveform, it is impossible to say exactly how
much current the MOV capacitance allows through. I suggest you try an
experiment of removing one of the MOVs and see how much cooler the
resistor runs.

They were used on the input side of large switching supplies for
minicomputers, and some later mainframes. I pulled about 100 of them
from the multiple switching supplies in an Amdal mainframe about 10 or
12 years ago.

Don't forget about "soak", also known as dielectric absorption or dielectric hysteresis. In some capacitors, particularly electrolytics, charge "soaks" into the dielectric and can take from seconds to days to work its way out. The result is a "discharged" capacitor that seems to spontaneously recharge itself. (One story I heard during my broadcast days was someone who put a screwdriver across a "discharged" capacitor. After he picked himself up off the floor, he found just the handle of the screwdriver. He was lucky his eyes weren't hit with molten metal. You'll often find large capacitors stored with a shorting wire across them -- a good idea.) I recommend leaving a heavy cliplead in place across the high voltage capacitors for the entire time you're working on the unit. Put some tape over the on/off switch and/or a tag on the plug to remind you to remove it before turning the power back on.

As a side note, the aquadag coating of a CRT is notorious for this. I've gotten a healthy bite off a CRT the day after it was discharged for an hour or more with a cliplead.

It would work to the extent that if you go 4x you could phase lock for a reference -- but you wouldn't have QPSK any more.

>the multiplier.

Well, that IS rather serious distortion...! :-)

True, the multipliers (or any following over-driven stage) will
strip off all the amplitude variations/modulations. But FM and
PM don't "modulate" the amplitude...even if the match APPEARS
that there are various amplitude sidebands present. Those
various resulting sidebands of FM/PM are the result of the
carrier "swinging" due to modulation and the various amplitude
sidebands are the RESULT of the constant swinging.

One of the ways of calibrating the DEVIATION of FM or PM, as
in checking a modulation monitor meter, is to (actually) look
for ZERO carrier frequency amplitude content, either by a
spectrum analyzer or a narrowband receiver. That's been an
accepted method of calibrating broadcast transmitter air
monitor meters for years and years. [for a hint on how that
is done, check them Bessel Function "zero-crossings" found in
many texts to derive the modulation test frequency and the
deviation]

Multiplying the carrier of FM/PM changes the DEVIATION of the
carrier (frequency for FM, phase for PM, a little of both
actually when there is some distortion happening). The rate of
change of the modulation itself has NOT changed, hence no
"chipmunk" voice sounds. Note that, all youse guys what is
locked into AM thinking. :-)

For a good treatment of the various modulation processes, I suggest "Electronic Designers' Handbook" by Robert W. Landee, Donovan C. Davis, Albert P. Albrecht, McGraw-Hill 1957, section Five (45 pages). Vacuum tube oriented (note copyright of 1957) but the modulation basics are there...the basics apply to all active devices.

For "chipmunk sounds" (which I used to do for funsies at WRRR many yarns ago) just use a tape deck with a different speed capstan for play-back. The rate of change of modulation is altered by the fractional (not integer) tape transport speed, thus the change in voice frequencies. The same thing can be done with recorded digital audio recovered with a DIFFERENT clock rate on read-out compared to sampling/recording. That's not just "multiplying frequencies" but rather changing the RATE OF CHANGE of the WHOLE sound. Not the same as multiplying just the carrier wave.

"Chipmunk" secret, the easy way: Use a 50 Hz capstan on the Magnecord reel-to-reel to record, play back with the standard 60 Hz capstan to get the increased rate of change of sound. Done in 1956, hardly any transistors on the market then, certainly NO integrated circuits having on-board A-D things. :-) Alas, reel-to-reel analog tape units are things of antiquity in 2005. :-)

I've got a related story to tell: I saw many years ago two guys try to jump start another guy in the winter time. I only saw a few seconds and surmised the following. These guys must have used the jumper cables to connect the two twelve volt batteries in series, not parallel. Why? The jumper cables were, themselves, literally smoking and not just a little bit. Figure 24 volt power at, what, something like 500 amps(?) split between heating up the interior of the two batteries and those jumper cables (that are usually like #4 or #6 gauge?). How many seconds would it take for on the order of 5000 watts to cause jumper cables to get up to 200-300+ degrees Farenheit? Those guys scrambled to tear those cables off the batteries and I could tell by how they were handling the cable that it had to be hot. They could have warped the lead plates.

Yep, I can vouch for this effect. I've seen it, too. Short the cap with
alligator clip-tipped wire for a few seconds if you want that voltage down
to microvolts. I think it is not "soak" but simple RC time constant decay.
Just like radioactive half-life. Residual voltage on a cap _never_ goes to
true zero, only according to the decay equation. However, there is a
so-called "electret" effect which really sounds like your "soak" effect.

After he picked himself up off

3238. TAKE A MINUTE EVERYONE

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-15 00:40:57 UTC
From: Edward Pereira <pereira_99@sympatico.ca>
Message-ID: <vDDBe.10625$6e3.647578@news20.bellglobal.com>
Source record: 18122

Basic Facts A while back, I was browsing these newsgroups, just like you are now, and came across an article similar to this that said you could make thousands of CASH within weeks with only an initial investment of $6.00 plus stamps!
So I thought, "Yeah, right, this must be a scam!" But like most of us I was curious and kept reading. It said that if you send $1.00 to each of the 6 names and addresses listed in the article, you could make thousands in a very short period of time.
You then place your own name and address at the bottom of the list at #6, and post the article to at least 300 newsgroups. (There are about 32,000 of them out there and that's quite a large market pool). No catch, that was it. Even though the investment was a measly $6, I had three questions that needed to be answered before I could get involved in this sort of thing.
Pay Attention 1. IS THIS REALLY LEGAL? I called a lawyer first. The lawyer was a little sceptical that I would actually make any CASH but he said it WAS LEGAL if I wanted to try it. I told him it sounded a lot like a chain letter but the details of the system (SEE BELOW) actually made it a legitimate legal business.
2. IS OK WITH THE POST OFFICE OR IS IT MAIL FRAUD? I called them: 1_800_725_2161 and they confirmed THIS IS ABSOLUTELY LEGAL! (See 18, h sections1302 NS 1341 of Postal Lottery Laws). This clarifies the program of collecting names and addresses for a mailing list.
3. IS IT RIGHT? Well, everyone who sends me a buck has a good chance of getting A LOT of CASH ... a much better chance than buying a lottery ticket!!! So, having these questions answered, I invested EXACTLY $7.92 ... six $1.00 bills and six 32 cent postage stamps ... and boy am I glad I did!!! Within 7 days, I started getting CASH in the mail! I was shocked! I figured it would end soon and didn't give it another thought. But the CASH continued coming in. In my first week I made between $20 to $30. By the end of the second week I had a made a total of $1,000.00. In the third week I had over $10,000.00 and it was still growing. This is now my fourth week and I have made a total of just over $42,000 and it's still coming in .....
It's certainly worth $6.00 and 6 stamps !!! Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more CASH than you thought possible by doing something so easy! Suggestion: Read this entire message carefully! (print it out or download it.)
Follow the simple directions and watch the CASH come in! It's easy. It's legal. And, your investment is only $6.00 (Plus postage)
IMPORTANT: This is not a rip off; it is not indecent; it is not illegal; and it is virtually no risk it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends.
PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or more

can be yours in 20 to 60 days.
This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the CASH made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list.
Here are the 4 easy steps to success:

STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery). Place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelop es, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1_800_725_2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses:

#1) J.E. Grey 245 Stone Bridge Ct. Fredericton, NB E3A 1J2, Canada
#2) R. Hanson 1214 Junor Ave. Saskatoon, SK S7L 7K1, Canada
#3) Leo Dapanas PO Box 6453 Stockton, CA 95206
#4) D.DiBenedetto 226 Pruden st. Thunder Bay ON. P7C 2J8 Canada
#5)Jeff Anderson 4833 N County Rd 11 C Loveland, CO 80538
#6)Edward Pereira PO Box 12, 4-1855 Dundas St. E., Mississauga ON. L4X 1M1 Can.
Are You Paying Attention? Good.

STEP 2: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list.

STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 300 newsgroups. (I think there are close to 32,000 groups) All you need is 300, but remember, the more you post, the more CASH you make! This is perfectly legal! If you have any doubts, refer to 18 Sec. 1302 & 1341 of the Postal lottery laws. Keep a copy of these steps for yourself and, whenever you need CASH, you can use it again, and again. PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are a person of integrity, the program will continue and the CASH that so many others have received will come your way.
NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good

idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of CASH in CASH!!! What an opportunity for only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you're in business!

___DIRECTIONS _____ FOR HOW TO POST TO NEWSGROUPS

Step 1) You do not need to re_type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this letter, and select 'copy' from the edit menu. This will copy the entire letter into the computer's memory.
Step 2) Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list.
Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to.
Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on_line forums, message boards, chat sites, discussions.)
Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations...THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup!
REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE CASH YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 300 That's it! You will begin receiving CASH from around the world within days! You may eventually want to rent a P.O.Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.**
Now the WHY part: Out of 300 postings, say I receive only 7 replies (a very low example). So then I made $7.00 with my name at #6 on the letter. Now, each of the 7 persons who just sent me $1.00 make the MINIMUM 300 postings, each with my name at #5 and only 7 persons respond to each of the 7 original 7, that is another $49.00 for me, now those 49 each make 300 MINIMUM posts with my name at #4 and only 7 replies each, I will bring in an additional $343.00! Now, those 343 persons turn around and post the MINIMUM 300 with my name at #3 and only receive 7 replies each, I will make an additional $2401.00! OK, now here is the fun part, each of those 2401 persons post a MINIMUM 300 letters with my name at #2 and they each only receive 7 replies, that just made me $16,807.00!!! Those 16807 persons will all deliver this message to 300 newsgroups with my name at #1 and if still 7 persons per 300 Newsgroups react I will receive $117,649.00! With an original investment of only $6.00! And some stamps. AMAZING! When your

name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday? JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, "what if the plan is played out and no one sends you the CASH? So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups pay your taxes. By doing this you prove your business intentions. Keep an eye on the newsgroups and when the cash has stopped coming (that means your name is no longer on the list), you just take the latest posting at the newsgroups, send another $6.00 to the names stated on the list, make your corrections (put your name at #6) and start posting again.

NOTES:

*1. In some countries, the export of the country's exchange is illegal. But you can get the license to do this from the post office, explaining the above statements (that you have an online business, etc. You may have to pay an extra tax, but that's OK, the amount of the incoming CASH is HUGE! And as I said, a few countries have that restriction .

*2. You may want to buy mailing and e_mail lists for future CASH. (Or Database or Spreadsheet software.)

*3. If you're really not sure or still think this can't be for real, please print a copy of this article and give it to someone who really needs the CASH, and see what happens.

*4. You will start getting responses within 1_2 weeks, it depends.

ALSO REMEMBER SEND YOUR $1 OUT TO EVERYONE ON THE LIST, EVEN IF THEY ARE NOT FROM THE U.S. OR CANADA.

GOOD LUCK AND ENJOY!!!

I built this two 811-a linear amplifier way long ago. Basically ave power 300 watts DC input. So, I made my own parasitic suppressors (turns of wire over, say, a ten ohm two watt carbon resistor. Or adjust turns). This was for a 75 meter phone band.

So, on launch day it sits there like a scared bird. Turn on fil power, plate power (this is grounded-grid for stability and minimal if not zero need for neutralizations), and tune (no drive) the plate capacitor. Result: dang, RF output through the power meter AND smoke comes out the top of the amp and I stand up, look down, and the coils of wire (made of #22 or 24 gauge wire, can't remember) around the resistors are glowing red hot! Too many turns of wire, so next time around I cut back to half and all was OK. Including no self-oscillation in the two 811-As.

That's called trial and error. Or, try, smoke, fix. Like if ready, fire, aim does not work, change the order to ready, aim, fire.

After reading all the other replies up to this moment, let me ask if you:
1. remove the radio (i.e. run the amp without the radio connected at all)
what do you get (if any reading of forward and/or reflected power), and
2. leave the radio connected to the amp, but run the amp without drive
power at all, then what do you get?
3. Can you vary the drive level (say down to lower levels) and still see
the SWR go up.
From what was written below, its not clear for sure if you are implying
that the amp did have a proper level of RF drive or not. But, I'd still be
interested in knowing if you get forward power and/or reflected power with
the amp turned on but without drive. I've actually had amplifiers where
the application of power and certain tuning conditions cause extra
frequencies to come out in addition to what was supposed to come out. And,
sometimes I got self-oscillation if the amplifier was NOT being driven
with input drive.

Yup. Formally "dielectric absorbtion". In a lot of types of
capacitor, enough stored charge can come back out, over the course of
a few minutes, to raise the open-circuit terminal voltage of the cap
to a significant percentage of its fully-charged level, even if you
had previously discharged the cap all the way to a zero reading.

It can be enough to give you a nasty bite.

Thanks for the response Joel. So if I understand correctly, Q is
basically an indicator of how well the LC circuit resonates? Could you
think of Q as the inverse of a dampening coefficient?

If so, I guess ideally you'd get the best Q with an iron-core inductor,
thick windings, and as few windings as possible?

I thought "computer grade" was either a marketing name, or at the
very most defined a certain design of capacitor.

In other words, they weren't designed for computers, but saw a lot of
use in them. They weren't cheap electrolytics of the type you'd
see in the average consumer equipment of thirty years ago.

You'd see them promoted in the surplus ads, and the ones I remember
were metal-cased, and had screw terminals for connections. I still
have one around I bought at a hamfest for a 12V power supply. It
was about 10,000uF (which was a fairly large size capacitor circa
1973 or so), had a voltage rating of about 16volts, and was the size
of a can of coke. Obviously a lot more impressive than the average
electrolytic of the day.

So once you had that style, it wasn't whether they were used in
computers or not, so of course you could have high voltage "computer
grade" capacitors.

I have no idea if it was a marketing ploy, "hey those are used in
computers [which were still uncommon at the time, and usually big
and very expensive], they must be good capacitors", or if there
was something about their design that made them better than the
average electrolytic of the time.

If I may jump in....
The case of crystal receivers is somewhat different than a "powered"
radio in that you want to keep things at as high a Q as possible to
match the high impedance of the circuit. High Q is desirable in any
case but moreso in a crystal set.

After having established a good high Q with the LC configuration you can
count on the circuit/antenna loading it down somewhat so then it becomes
a matter of selecting appropriate diodes, decoupling the ant, etc. so it
always helps to start out with as much as possible.

Textbook Q of more C/less L is dictated simply by resistance. In
practice, at least for BCB xtal radios, the dielectric of the coil, skin
effects of the wire, interwinding capacitance are the key players.
Thats why certain coil dimensions, use of litz wire and certain winding
techniques can generally be counted on for the highest Q.

The Q of a coil, and/or complete circuit, will have a curve of its own.
With BCB, what is good at 600kc may be better at 800kc and
(relatively) terrible at 1600kc.

I've had good success with ferrite toroids approaching Q=400, although ferrites are by nature very unpredictable Q-wise. This is as good as one can expect with something like a 3-4" diameter coil of #18 wire on a good coil form. OTOH, the toroid stops there. That same 4" coil wound with 660-strand litz can get up into the Q=800 stratosphere with a basket-wind technique.

There's always a downside. A big, hi-Q coil needs to be kept well away from ANYTHING or else the Q will take a nosedive and then lead capacitance starts biting you from the backside.

I find xtal sets fascinating. I've been radioing for 35-40 years and never gained a full appreciation for L, C and Q until I got into DXing with xtal sets. Logged 105 BCB stations in the competition earlier this year including two in Brazil!

No, it's not a simple time constant -- the slope is much different. A reasonably good model of it is a series R, shunt C, series R, shunt C, etc. A large number of Rs and Cs with various time constants have to be used to imitate it reasonably well.

I don't know about an "electret effect". An electret is a dielectric with a permanently trapped charge, so it produces a static electric field. It's the analog of a magnet, with permanently trapped flux and producing a permanent magnetic field. A magnet that's not moving can't produce a current (much to the dismay of the perpetual motion crowd), and an electret that's not moving can't produce a voltage.

>

That's for an entirely different reason -- to protect the meter from damage, rather than the user.

Jim,

If they were used in a Japanese radio (Alinco Icom Kenwood Yaesu) you may be
able
getting replacement parts from the US representative.

I wanted some CFJ455K8 filters. They were used in the Alinco DX-70. I
contacted Alinco America
and ordered a couple of filters. The price was reasonable since they were
removed from parts radios
Alinco had on hand.

>Thanks for the response Joel. So if I understand correctly, Q is
>basically an indicator of how well the LC circuit resonates? Could you
>think of Q as the inverse of a dampening coefficient?

In a way, you might think that. For going to more advanced things
besides "simple AM receivers," I'd suggest thinking of Q as a
built-in LOSS element.

For parallel-tuned circuits, the loss can be modeled as a resistor
in parallel with the L and C. This equivalent resistor value is
the reactance of either L or C (they are equal at resonance)
multiplied by Q. A high Q indicates least loss in a parallel
circuit, a high value of equivalent parallel resistance.

But, for series-tuned circuits, the loss is equal to a resistor
in series with L and C. That resistor value is equal to the
reactance of either L or C divided by Q. A high Q in a series-
tuned resonance would have the lesser value of series resistance.

>If so, I guess ideally you'd get the best Q with an iron-core inductor,
>thick windings, and as few windings as possible?

Yes and NO. Q will vary by MANY things. Generally, physically
big coils will have higher Q, physically big windings will have
higher Q. Shape factor, like length versus diameter of a
solenoidal winding has an optimum value. Nearby shielding will
tend to reduce Q; one reason why toroidal forms have higher Q
than solenoidal or cylindrical windings.

CORE MATERIAL IS FREQUENCY SENSITIVE! "Iron core" has to be
defined. Power transformer laminations are okay at up to
about 10 KHz and then become more lossy with increasing
frequency. Special iron (tape shape, usually) is used for

higher frequencies in the supersonic range. At LF and higher, various kinds of iron POWDER are used to enhance Q (within their specified frequency range).

Q applies to capacitors also...and is affected by things like plate area, plate material, dielectric if other than air, and (to some degree) physical shape factors. Generally, though, the Q of most resonating capacitors is 10 to 100 times larger than inductors and can usually be neglected in most calculations of tuned circuits. Inductor Q rules! :-)

For self-education, I'd suggest spending some time with a good Q Meter and trying out measurements on various kinds of inductors. That will probably give you the best Q picture in your mind.

>How well-defined is the gain for a cap-coil loop, like in an AM radio?
>(i.e., how fast does the gain droppoff as you move up or down from the
>'tuned' frequency?) Is it a function of L and C? Or just frequency?
>(different combinations of L and C will tune to the same frequency, but
>is the gain the same?)

"Gain" of a crystal radio depends on the bigness of the antenna.

If you are talking about a loop antenna on an AM [BC band]
radio, then it's a different story. The loop antenna on an
AM receiver is small/tiny/micro-stuff relative to the 200+
meters of AM BC wavelengths. The received signal VOLTAGE
is directly dependent on the number of turns in that loop and
the physical size of the loop.

A loop antenna is into what some folks call a "magetic antenna";
i.e., very small relative to wavelength, therefore it intercepts
only the magnetic part of the electro-magnetic wavefront radiated
by a transmitter. The more turns in that loop, the greater the
voltage induced in the loop.

A humungous-long wire is going to supply the greatest amount of
POWER to a crystal receiver. POWER drives the headphones. But,
the amount of power coupled in involves IMPEDANCE and that, right
away, gets into a complicated mess of more electrical rules.

Simple crystal receivers want to keep impedances very high at
both input, middle, and output. ["crystal" or piezo-electric
headphones are the best for that, next best is the highest
impedance magnetic headphones (2000 Ohms or higher) you can get]

For the typical parallel-tuned L-C input to a crystal set, the
inductor Q will make a difference. It must be as high as is
practical; Qs of 200 to 300 have been done. But, the Q of the
coil is dependent on a LOT of different factors which I noted
in the other message.

>How come the coils on many of the CR schematics I've seen have multiple
>tap locations? It seems that with a variable cap, you should be able
>to tune to whatever frequency that's in your range.

Mostly, that is just old-time tradition! :-) [I kid you not]

The formula for resonance is: F^2 = 1 / (39.478 * L * C)

With F being frequency in Hz, L in Hy, C in Fd.

To check this out, a 2.5 mHy inductor and 1000 pFd capacitor will be resonant very close to 100 KHz.

The maximum to minimum variable capacitance ratio is equal to the square of the maximum to minimum frequency tuning ratio desired. That's about IT.

"Taps" on a coil can be to select different inductance values for resonance with limited-range variable tuning capacitors. Note: Back in the prehistory of radio, like around the 1920s, variable capacitors were expensive and not so easy to get. A few old-time crystal sets "tuned" via lots of coil taps using a fixed parallel capacitor. I had a Philmore crystal radio kit back in 1946 that did that. Very cheap kit. It worked, so-so.

Presupposing a loop antenna that is resonated by a variable capacitor, its "gain" is going to be greatly influenced by its Q or Quality factor. The higher the Q, the greater the voltage into the headphones. However, the Q may NOT be the same over the approximate 3:1 frequency span of the AM BC band. [again, too many variables as noted in other message]

The Q of that L-C circuit is going to be "spoiled" by the impedance/resistance of the headphones. Those headphones are in parallel with the parallel-tuned L-C circuit. The higher the impedance/resistance of the headphones, the least effect it will have on the Q of the L-C resonant circuit.

Somehow my browser failed to pick up your initial message so this is a reverse-order answer. Sorry about that.

I think you'll have to say what is acceptable to you and define what you mean by "spectral grass". In terms of phase noise, you'll do better with a normally designed DDS than you will with a normally defined PLL. For data on what a DDS can do rephase noise, look at various models of synthesizers on the PTS web site.

Now of course there are spurs to contend with in any DDS design, but discrete spurs are not what I would call "spectral grass". If spurs are indeed your issue, you can go to a 14 bit DDS (AD9951 or others) and get at least spurs at least 80 db down, or add filtering to the DDS output.

I would like reverse a PWM signal of 500Hz to use on an IC. I would like to use a pnp npn but I get clipping of the signal at low voltages, help please

Just about exactly. You'll find the term "damping factor" (sometimes "damping ratio" or "damping coefficient") often used in many situations involving network analysis and control systems, usually represented by the lowercase Greek letter zeta. And it's numerically equal to 1/(2Q), so Q is exactly 1/2 the inverse of the damping factor.

When the damping factor is 1 (Q = 0.5), a second order circuit is said to be critically damped.

Loop antennas do suck on a xtal set for that reason but "bigness" can
suck equally if not done right.

You know how you read all those old texts about using nice glass
insulators and keeping the wire away from anything? In everyday
practice you can do pretty well what you please with wire antennas and
powered radios and notice very little difference. Once you get into the
realm of truly hi-z installations those tree leaves brushing against the
wire become noticeable.

Acutally the best is a good matching xfmr and sound powered phones.
Those old 1920's 2k headsets are relatively deaf. But you did specify
"simple crystal receivers" and it that case it doesn't really matter.

Q in excess of 1000 is readily achievable. 200-300 is a starting point
on a decent dx set.

Most of these old ckts relied on a 17 or 21 plate cap which was in the
400-500 pf range. They would tune the entire band at full tapping. The
tapping allowed a guy to really nitpick his tuning for two
reasons...ease of fine tuning and higher Q at the best combination.

The total spur power seems to be more or less constant in the
traditional DDS. However the distribution of the spur power varies
constantly with the frequency (i.e. phase accumulator increment).

At some settings there will be a huge number of low level spurs more
or less evenly distributed along the frequency band. I assume that the
OP is calling this spectral grass.

However, at some specific phase accumulator increments, the spur power
is concentrated on just a few discrete frequencies, adding up to
easily visible spur peaks, but between these peaks the spectrum is
clean (only thermal noise).

If the discrete spurs cause problems, it would be a good idea to check
if the frequency management could be modified in such a way that the
spot frequencies that cause large discrete spurs are skipped.

OTOH, if a very clean signal is required in a narrow band, it might be
a good idea to concentrate the total spur power into a few discrete
spurs outside the band and thus have a clean band of interest.

> I have not seen much description on the solid state amp except that it has
MRF455 transistors. Because these devices were a favorite in the manufacture
of CB amplifiers, I am suspicious that the only output filtering is a HPF
set to cutoff around 30MHz.
So, running this amp on the lower HF bands would allow a lot of harmonic
energy to appear at the output.

> only puts out about 100 watts.

When I had this it was caused by arcing at the antenna. VSWR perfect with low power, but it even made an audible noise when you screwed the power up.

1 - Try this using a band-pass filter:
RADIO-->2 TRANSISTOR AMP-->SWR METER-->FILTER-->DUMMY
If amp churns out shit then the filter will reflect it. If VSWR is good, then:

2 - Eliminate your feeder (could be breaking down):
RADIO-->2 TRANSISTOR AMP-->SWR METER-->FEEDER-->DUMMY
When you do this you may even see a duff contact/joint.
If the feeder insulation is breaking down then VSWR rises again. If not then:

3 - Check out the antenna / balun / feed points for strands of wire, smoke, etc.

From: Derek Twynham <derek.photo@hotmail.com>
Message-ID: <db8cp7$f7n$1@news.al.sw.ericsson.se>
Source record: 18144

> How do you measure the impedance of a broadband transformer for a RF
> transistor amplifier? I'm referring to the input and output broadband
> tranformers just before and after the transistor finals.

You don't! The broadband transformer reflects the load impedance back to the driving stage. In other words, if the turns-ratio is 1:1 then the input impedance of the transformer is equal to the load impedance.

If your load is 50 Ohms and you want to match a 10-watt transmitter, with a 12v supply, then you need to calculate the impedance ratio. The transmitter output stage impedance (in Ohms) is

(Vsupply squared) / Watts

With 12 v supply, the output impedance of a 10- watt amplifier is
(12 x 12) / 10 = 144 / 10 = 14.4 Ohms.

The transformer impedance ratio is therefore:
14.4 : 50 = 1 : 3.5

The transformer turns ratio is therefore Sqrt (impedance ratio)
= 1: 1.8 (close enough to 1:2) step-up.

>

>
> Roy Lewallen, W7EL

I repeat, changing the cable length will change the swr *seen* at the
transmitter end significantly. As w7el says, changing the cable length
will change the impedance looking into the cable. Since most common,
inexpensive swr meters are calibrated for use with a 50ohm load, the actual
swr readings will be dependent upon the impedance presented to the swr
meter while looking into the cable. Although the actual swr may not change,
the swr that you see may very well change. A 7 foot stub represents an
eighth wavelength all the way down to 60m. This is enough to present an
impedance change.

Well, if you want to get technical about it, yes. All those layers of foil
all, individually, add up to all of those Cs and Rs.

> I don't know about an "electret effect". An electret is a dielectric with a
> permanently trapped charge, so it produces a static electric field.

I doubt if there is very much in the universe with a real, practical
permanence. The second law of thermodynamics says that trapped charge is
going to try hard to become untrapped.

It's the
> analog of a magnet, with permanently trapped flux and producing a permanent
> magnetic field.

Most magnets that I've heard about will slowly lose their magnetism via
one of many mechanisms.

A magnet that's not moving can't produce a current (much to
> the dismay of the perpetual motion crowd), and an electret that's not moving
> can't produce a voltage.

In a laboratory, once, I made an electret out of, basically, frozen water.
The various pieces of these electrets, bathed in liquid nitrogen, behaved,
qualitatively, like little magnets. Bring one near another, and whatever
"pole" was at some point on one piece would spontaneously jump,

appropriately, to the piece I was holding.

An electret that is not moving can't produce a voltage? Semantics. There _will_ be an electric field between one pole and the other and it _will_ be measureable and calculable and the results will be in volts regardless of whether the electret is "moving". The units can be expressed in more than one way depending on reference systems, definitions, and goal of the measurement or calculation.

>>

This coming Sunday....

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday July 17th 2005
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and

Nice answer, Roy. That was my knee-jerk, too.

Joseph, remember, the problem isn't only "stopping them from getting out of the amp...". Those other frequencies are some sort of parasitic in the amplifier. Besides being stuff you don't want going to the antenna, they are robbing your amp of the ability to amplify the frequencies you DO want amplified, and they are unnecessarily heating up your transistors and sapping their life.

So first, keep them from being generated, then stiffen up that low pass filter so anything that does get created is way, way down. Far lower than what will show up as an apparent SWR problem.

..

Nice website you have there. The CFX455 filters have a center frequency of
455kHz, while the the CFX450 filters have a 455kHz center frequency.

>dealing with the proof that electricity is really smoke....

A local (and now retired) engineering faculty member has an after-dinner
speech in which he "proves" that "electricity is black and heavy"!

For example, in an automobile, electricity is stored in the battery.
What color is the battery? Black!
And it is quite heavy for its size.

And on and on and on!

But electricity _is_ really smoke. They burn coal at the generating
station and it travels through the wires to your house, where it makes
everything work. Then the used smoke goes _back_ through the wires (why
do you think they call them "return" wires, eh?) to the generating
station where it goes up the smokestack.

If something should break then some of the smoke will leak out right
there in your house right before the thing stops working.

And that's how you know that electricity is smoke.

Howdy:

I got just what you are looking for... how about the 'WWII Prison Camp Short-wave Receiver' ?

The circuit is claimed to be from, "United States Army in WWII The Technical Services, The Signal Corps: The Outcome, U.S. Government Printing Office, 1966."

Check the circuit at:
http://www.webex.net/~skywaves/SPY/spy.htm

I collected parts but never had a chance to build it---old metal canteens are hard to find.

3273. Finishing Aluminum

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-16 00:30:33 UTC
From: RadioGuy <nospam@nospam.com>
Message-ID: <JyYBe.425340$cg1.138579@bgtnsc04-news.ops.worldnet.att.net>
Source record: 18155

Howdy:

Its been a common practice with me to finish the aluminum surface of a chassis or box with an immersion into a caustic solution followed with a coating of clear acrylic spray---I like the satin finish it produces. I normally use lye that I regularly found on the shelves of our neighborhood hardware stores. However, I've been having a harder time of finding the flaked lye that I have used over the years for that purpose. I have used 'Lewis Red Devil Lye' that I found at Ace Hardware.

A project that I am currently working on made me think of trying a substitute for lye with an item that I seem to find everywhere. Often found in the automotive stores is a product that is referred to as a 'cleaner/degreaser' or 'heavy duty industrial cleaner'. I have seen it marketed as 'Purple Stuff' yet I purchased a gallon called 'Right Stuff (Purple Stuff Concentrate)' manufactured by Sunbelt Chemicals, Palm Coast, Florida, 386.446.4595. Nevertheless, the contents of both bottles have a characteristic purple color and contains (besides sodium hydroxide) a component derived from citrus---but more importantly, the label states that the product is NOT TO BE USED ON ALUMINUM!

I finished the surface of both halves of a mini-box by immersing them into a solution, by volume, of 1 part 'Right Stuff' to 8 parts warm water (I used 1:8 for no particular reason---It just happened that way). The surface of the aluminum began to bubble rapidly, but not uncontrollably, causing a fine white froth to appear on the surface of the solution. I let the mini-box soak for 30 minutes whereupon I removed them and placed them into a bucket of water. I found that the removal of the black residue is easier to achieve if I wash the aluminum parts while they remain under water---a sponge or cloth works fine and a Q-Tip removes the residue from corners. I observed that as the reaction proceeded the purple color of the solution became clear.

Needless to say, I am entirely satisfied with the results. The dilute solution of 'Right Stuff' provided a uniform satin finish identical in appearance to a solution of lye (sodium hydroxide). If you can't find lye I suggest a solution of industrial cleaner possessing caustic properties. The next time I use 'Right Stuff' I will increase it by 1 part just to see the result. The reaction liberates hydrogen gas---use adequate ventilation.

RG

That's pretty good, but I seem to recall another slightly different
version of the joke but with some really clever line about the purpose
of insulation (and a half-believable rationale [rationale does not mean
scientific, however). Anyone else remember more of the details of this joke?

Sounds logical to me.

My favoite is the Dark Sucker Theory (light is the absence of dark, and
light bulds suck dark). Do a google on it for lots more info, probably more
than you ever wanted to know... :-)

And thusly another thread morphs far off topic...

3276. Heater voltage for Avantek YIG?

Thanks all. Tom, I've been in electronics thirty years or so, but always solid state.Now I'm going backwards to boatanchors. I know most of the old sayings such as "keep one hand in your pocket" etc., but I'm more interested in practical considerations of draining capacitors, proper wiring techniques, and so forth. I know that even unplugged tube devices can jump out and get you, and I'd like to avoid this...especially in high power RF amplifiers. I've got Bill Orr's handbook, years of old magazines from the 50's, and ARRL handbooks; great circuits but little in technique. It's like school, great on theory but troubleshooting is only taught in the doing.

I still have a couple of cans of Red Devil "in stock" after my last
project. That was the rejuvenation of a 20-year-old Yagi antenna. I
built a plastic sheet lined trough outside that was long enough to
hold the longest piece of tubing and had at it.

Good to know. You might find that a dip in vinegar will help with the
removal of the black smut.

If you want a really satiny surface, another trick I have used is to
sand the surface with an orbital sander and medium grit wet-dry paper
lubricated with light oil. It's a messy process but leaves an
interesting surface with the little "orbit" scratches and it's a good
way to recover badly scratched surfaces. Etching afterwards with lye
"softens" the effect and of coarse cleans the surface.

One thing to consider is to make and use a "chicken stick". Don't
touch anything electrical until you have touched it with the chicken
stick.

This is essentially a ground wire (to a solid ground) with a well
insulated handle. To avoid component damage, add a low ohmage, high
wattage resistor in series.

A chicken stick is routinely used in commercial HV equipment, and
power company linemen have a portable equivalent.

Better to be a live chicken than flambeed.

Thanks... I didn't know that! I often wondered if there was an easier way
to remove the black residue.

I'll give that technique a try.

Awhile back I heard that after the metal is finished in a lye bath then
boiled in a solution of color dye (RIT) a colored, metallic finish, can be
produced---one of these days I'll try it on a scrap piece.

On simple projects I print or photocopy text then affix them onto to the
aluminum surface (after a first coat of acrylic on the aluminum) with white
glue then with multiple sprays of acrylic affix them permanently to the
surface. It worked real nice with a bandpass filter project---I secured the
graph of the filter characteristics onto the minibox for reference.

>
> THanks!
>

My 1990 Avantek book doesn't show that part number or anything close to it, but the heater voltage spec on all of the (many) YTOs it does list is 20-28V. They specify power consumption rather than current: 2.0 watts at 0 degrees C, 1.5 watts at 25C.

So I'd probably try a 24V supply, current limited at about 150 mA to start with. After the heater warms up, the current should fall to the 60 mA neighborhood. If it does, then it would be safe to assume that the 20-28V spec applies to yours.

i need a variable for a receiving loop antenna. does anyone know how to determine the area of plates for a given value of cap? for example i need 365 pf. two half circle plates would be handy, separated by a piece of plastic or card stock. what surface area for each plate would approximate that value? does two stator plates with one rotor between them increase the value if compared to one plate each?

for each facing pair, (ie with two fixed and one moving in
between, you'll get two faces)

C=eA/d e=permittivity of free space, A=area, d= separation.

But you must use real scientific/engineering units, not those Yank Hillbilly
ones.

For a parallel-plate capacitor, capacitance equals

0.0885 e[r] (N - 1) A / t

where A is the area of one plate (in square inches), N is the number
of plates, t is the thickness of the dielectric (separation between
plates, in an air-variable cap) measured in inches, and e[r] is the
dielectric constant of the dielectric (1.0 in the case of air).

A cap with two stator plates and one rotor plate would have twice the
capacitance of a cap with one stator and one rotor, all else being
equal and neglecting parasitic effects.

The spacing between the plates is an important factor as well.

You will need to construct it mechanically solid enough that the
spacing does not change much.

The dielectric material properties will have an effect as well,
although smaller.

Happy trails,

==========
In the May 2005 issue of 'Electron' (mag of VERON ,the IARU affiliated
society in the Netherlands) there is an article , by PE1LKT ,on a homebrew
'sliding 'capacitor made of pieces of double sided printed circuit board.
5 plates are fixed with 4 plates sliding in between.
The fixed and sliding plates fit inside grooves ,made in 2 pieces of timber
or polystyrene (alternatively inside glued strips of such material). The
sliding plates are tapered at one end and straight at the other end where
they are also bolted together with double sided PCB material spacers or
bolts and washers. At that end is also a soldered nut which suits a threaded
bar which is supported by a simple 'hose type bearing' with the end coupled
via a piece of rubber or plastic hose to a fixed in-line electric screw
driver.
The electric motor is operated remotely via a three position switch for '
right hand rotation' - 'off ' -'left hand rotation'
The fixed plates are obviously also galvanically connected at the far end
away from the moving plates .

This variable capacitor is used for a transmitting magloop and hence is
subjected to high RF voltages ,hence the plates are appropriately spaced .
Spacing could be minimised for a RX loop

The above variable cap has a capacitance of approx 400 pF ,requiring fixed
plates each with an area of 210 x 170 mm (357 cmsq equals approx 55 inch
sq). The sliding plates are slightly shorter.

For a RX loop requiring less plate spacing the plate area can be reduced.

>to where I might get such a beast?

Usually known as a "rotary encoder". They normally have two outputs,
in a phase-quadrature arrangment. These can be decoded to create
up/down/clock pulses using dedicated ICs (HP makes 'em), or via a small
collection of discrete TTL logic chips, or via a simple software
routine in a PIC micro or similar (which is how I'd probably do it
these days... I wrote a simple state-table routine for an 8051 some
years back which worked out quite well).

You'll probably want at least 64 counts per revolution, and probably
256, to get a nice smooth "feel" to the synthesizer tuning. Most such
use an optical code wheel and a pair of optosensors.

Digi-Key catalog lists quite a few such (all with their own shafts,
ready for panel mounting), but they aren't cheap. Mechanical rotary
encoders are less expensive, but less precise (fewer counts per
revolution) and possibly not as reliable or long-lived since they use
mechanical contacts.

For something inexpensive, consider the encoder in a wheel mouse. Also
most ball mice include two encoders for the ball.

Do you really need to build this? I know they (365 mfd variables) are hard to find (I'd love to find a cheap source, expensive sources on the internet want $10-15 each [google on "365 mfd" to find them]), but if you go to a thrift store (Salvation Army, etc.), you may find old transistor clock radios for $1-2 each that have miniature 365 mfd variables that will do just fine if you take a few minutes to de-solder them from the circuit board.

Depending on the application, mechanical encoders are pretty good, and
getting better. As a tuning control, in most cases something on the order
of 50 pulses per rev is pretty useable and avaliable in a mechanical
encoder. Much more than that and you are getting into the optical encoders
which do get kind of pricey. They -feel- really nice, though.

Most of the mechanical encoders Digikey carries are detented, so watch out
for that. The few that aren't are pretty decent. Mechanical encoders are
typically under $5, while the opticals are more like $50. But the nice
ball-bearing feel might be worth it, depending on your project.

..

For something like a receiver tuning control, even 256 steps/rev would sound 'jumpy'. However, you could gear it up mechanically so that even a small movement of the control produces several pulses from the encoder. That is exactly what happens in a mouse.

Try an old-fashioned cord drive, only in reverse.

Of course, you CAN build the capacitor, but unless you want to do it for fun and/or education, why re-invent the wheel? Dan's Small Parts and Kits sells several nice capacitors.

http://www.danssmallpartsandkits.net/

The capacitors aren't necessarily "dirt cheap", but a manufactured capacitor will be physically stable, insuring smooth change in capacitance as the shaft is rotated.

Actually, a stronger acid works better (quicker). The "blackness"
seems to depend on the alloy and it may still take light rubbing to
get the stubborn stuff off. I'm neither a chemist or metalurgist but
in my early days in a real engineering lab environment we had a "chem
lab" where they had tanks of caustic and acid (and Alodine) for
passivating aluminum and I learned a few things there. Always
remember to fully rinse any of this stuff off with lots of water.

Nice idea. I use the ruboff lettering (Datak) but of course they
don't have any BPF response curves, [g]

On a bare metal panel the homebrew inkjet waterslide decals work quite
well and you could do your response curve with that method.

As I understand it, the black stuff is usually referred to as "smut".
It's the other metals in the alloy, left behind when the lye dissolves
the aluminum.

Anodizing shops will follow the lye-etch with a plunge into a "bright
dip" acid bath to de-smut the surface and leave it nice and shiny.
Bright dip mixtures seem to vary - one I've seen mentioned is mostly
phosphoric acid, with a few percent of nitric acid added. Kinda nasty
stuff.

Yup. A common cycle seems to be: drill and sand, etch in lye,
bright-dip to de-smut, anodize to build up a porous layer of hard
aluminum oxide, boil in dye to color, seal.

One problem with the use of RIT color dyes is that they aren't all
that stable against UV, and can fade over time. There are
professional anodizing dyes which are more stable.

The Brother plastic-laminated labelling tapes seem to work fairly
well, also. I usually use the standard black-text-on-white-background
and then spray with acrylic. The black-on-clear might look nice on an
aluminum case, but I haven't tries this myself yet.

3307. Resistor frequency response

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-17 17:15:42 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <dbe3nuejh1@nwrdmz03.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 18188

FREQUENCY RESPONSE OF RESISTORS.

Program METALFLM.exe 41 Kbytes.

This program models small low-wattage wire-ended resistors including spiralled metal-film resistors. The model's equivalent circuit is a chain of T and L networks. Values of lumped inductance and stray capacitance are estimated by the program from the component's physical dimensions.

The component with it's terminating leads is treated as a lumped L and C non-uniform transmission line. The program computes input impedance from 10 KHz up to 5 GHz with the other end grounded. Fast and slow frequency sweeps are available to observe maxima and minima of Zin.

Max and min Zin are approximately related to the physical length of the component, including connecting leads, but occur at frequencies far higher than the usual and useful working frequency range.

The reflection cefficient and standing-wave-ratio are calculated with reference to Zo, Zo being the DC value of the resistor. The usefulness of the component as a dummy load or for other purposes at any frequency can then be ascertained.

The effectiveness versus frequency of solid carbon-rod resistors and multi-turn UHF chokes, which are of similar wire-end construction, can also be determined. Chokes can be wound over the bodies of high-value wire-ended resistors, the parallel resistance value perhaps having some desirable effect on the ultimate response.

Another use for resistors having a good high frequency response, or at least a known frequency response, is for ratio arms and switched resistors in impedance bridges and other measuring instruments.

Download METALFLM in a few seconds and run immediately.

EasyTrax is a freeware program Protel released for DOS computers years ago. it will run on Windows 98 in a DOS windowm too.

Do a google search and you'll find many sites that have it for download.

One note, it doesn't have surface mount pads, so it's through-hole or kludge in the SM parts.

Silver micas cost more and had a better spec for capacitance, temperature as
well as aging and are used in circuits where you want to minimize frequency
drift.
IIRC silver was plated somehow onto the higher grade mica whereas ordinary
micas used a lower grade o f mica and weren't plated or plated as well.

Hi folks,
I would have to ask a clarification regard to the TCXO.
They are found with output TTL, HCMOS and CLIPPED SINE WAVE.
It is just with respect to this last type that I would want to have
elucidations on when it is convenient to employ it, which the advantages and
the disadvantages and which the extension of spectral harmonicas.
In synthesis, from the plan point of view, which are the motivations that
they make to incline towards a Clipped oscillator?

Anticipated thanks.

Actually, 256 is getting too high in most cases. The "jumpiness" comes from the size of the step, i.e., the number of Hz per step. Encoders between 50 and 100 are probably the easiest to deal with. You generally want to make the step size small, like 1 or 10 Hz, but you don't want hundreds of turns to cover the band. At very high resolutions, the pulses can come very fast, so it gets tricky to distinguish the closure from noise. Of course, higher counts can be made to work, and in principle, can be made to work better. But generally, one is dealing with low level software and finite compute resources to read the encoder, so the very high resolutions can actually become somewhat problematic.

The TTL and HCMOS outputs will have (generally) square waves
which are rich in odd harmonic content. Clipped sine waves
have less overall harmonics...but the harmonic content depends
on the amount of clipping (presumably off the peak of the sine).

>In synthesis, from the plan point of view, which are the motivations that
>they make to incline towards a Clipped oscillator?

Depends entirely on the designer's choice. If this is a
purchased TCXO unit then a clipped sinewave output would
probably come through a buffer stage directly from the
internal oscillator output...which resembles a clipped
sine wave. For the purchased unit, having that output is
a convenience to the customer.

TTL and HCMOS outputs would be made from internal digital
devices, again a customer convenience to allow easy interface
to external TTL or HCMOS circuitry.

The clipped sinewave is the simplest output for a TCXO, it's usually just a capacitor connected between the emitter of the oscillator and the output pin. You have to be careful what you connect to it, it's possible to throw the temp compensation out of tolerance. Most CMOS PLL chips have a reference frequency input that handles it well. If you're rolling your own PLL from SSI or MSI chips, you probable want to build up a buffer to make the clipped sinewave into TTL or HCMOS levels, or pay extra for a TCXO with the needed circuit built in.

So what's a good inductance to DC resistance ratio for an inductor on
an xtal set? The one I wound is about 500uH, and I get a resistance of
3.2 Ohms.

Using the formula Q=2*pi*f*L/R, I get a Q for my coil of 981 (@1MHz).
But based on its performance, I KNOW it's not that good. I'm picking
up a couple stations at night, but just barely.

I was suggesting that you might prove that the MOV current is the
cause of the resistor overheating, by removing an MOV and applying the
input signal. I can't guarantee the input will work, correctly, however.

Ahem, have you guys agreed on what defines "jumpiness?" :-)

I'm into the actual receiver portion of a PLL-LO-controlled
HF SW BC receiver tuning in 1 KHz steps. The PLL and its
controlling circuitry are done and a 256-step Grayhill shaft
encoder is used with a shaft encoder decoder circuit from Dr.
Robert Dennis. That decoder circuit uses 3 HCMOS DIPs for
Up/Down counters having separate Up and Down clocks. One more
HCMOS DIP gate package is required for Up/Down counters having
a single clock input and having an Up or Down mode control pin.

> At very high resolutions, the pulses can come very fast,
>so it gets tricky to distinguish the closure from noise.

I didn't find it so. The Dennis Decoder will allow shaft
encoder rotation rates of 150 RPM with a 240-step shaft
encoder, no problem. Pressed faster, it can handle 300 RPM
or 5 revolutions per second...quite fast tuning. It is
easily comparable to the "old" tuning control on my Icom
IC-R70 which has an estimated 200 steps per revolution.

> Of course,
>higher counts can be made to work, and in principle, can be made to work
>better. But generally, one is dealing with low level software and finite
>compute resources to read the encoder, so the very high resolutions can
>actually become somewhat problematic.

While the BCD Up/Down counter ICs are getting rather scarce,
it takes only three more packages to "see" three-decimal-digit
resolution. Add another IC for four-decimal-digit resolution.
4-stage binary Up/Down counters are still being made, no problem.

Ain't no software for this critter...it's all hardware. The Up/Down counter drives the PLL divider directly (through a EPROM translator, preprogrammed, or through some more logic gates). Grayhill shaft encoder output is TTL/HCMOS level at +5 VDC into the encoder. Very fast jumps in handling the shaft encoder knob don't upset the counter chain.

If you want some nice decoder circuit schematics and a set of decoder waveforms, let me know at signature address below and I can attach the ZIP file (19 K) to e-mail.

If someone wants an Absolute position control, that could be done with an additional optical sensor and track that resets the Up/Down counter at all-zeroes. Not the same as a Gray Code multiple track and sensor encoder with a collection of Exclusive-Or gates to make it straight binary, but cheaper.

For BCB work the 'standard' is in the 220-240uh range for tuning with a ~365-400 pf cap. There's an (almost) infinite number of combinations you can use if you want to split the band into segments which sometimes has an advantage. But switches and tapped coils can also be Q-killers once you get into the Q stratosphere.

In practice the coil Q is determined primarily by the form dielectric, wire size, wire spacing, diameter/length ratio/neary coupling effects, etc. R is far enough down the list that its generally not even considered. When you do a DC measurement of coil R thats not representative of the skin effects and true RF resistance, thats why the textbook formula doesn't pan out.

If you want to make a fairly nice coil without getting into the expense of litz, check out spider-web coils and rook coils. When done with say 16-18 ga wire, and diameters in the 4" range you can get a pretty nice coil. With 166-strand litz (30-35c/ft) you'll note an improvement but by that time its time to start thinking about a good hi-q ceramic capacitor and circuit loading concerns.

The Rap-n-Tap forum is where to get some good info.
http://www.midnightscience.com/rapntap/ "Best coil" is a common topic!

>But based on its performance, I KNOW it's not that good. I'm picking
>up a couple stations at night, but just barely.

The "R" in the Q formula is an equivalent resistance at frequency,
not just the DC resistance. That equivalent resistance is made
up of many things: winding form factor, wire size, and the DC
resistance to name the major factors.

Q alone won't determine sensitivity. Sensitivity, without some
accurate numbers such as transmitter power output, distance to
transmitter, antenna gain/loss, is going to be a very subjective
item. Even with them available the numbers can turn out to be
rather off when listened to.

A couple of years ago now, I wound a loop for 60 KHz (WWVB
reception) using #14 electrical wire. It was rather cheap
at Home Depot compared to enameled "magnet" wire for a 500
foot length. Inductance came out roughly according to formula
but the low DC resistance didn't do much for the Q. At 60 KHz
the Q was only about 68. :-) Dimensions were about 2 1/2 feet
diameter, circular, with an aluminum foil electrostatic shield
over the top of 57 turns. In retrospect I should have used many
more turns of smaller wire, such as #26 AWG, since signal
strength is proportional to the number of turns for the same
size loop.

It could have been the insulation on the electrical wire that
reduced the Q. Unknown. Would have to wind a similar one in
"magnet" wire to find out. It was measured for Q and inductance
without and with the foil electrostatic shield with no discernable
changes in Q, only slight in inductance. As it is, it works well
enough, is presently in the attic above the interior workshop.
[size dictated by trap door access to that part of attic]

Years and years ago I fooled around trying to make an AM BC loop according to "expert instructions" from some magazine. Spent a lot of time cutting the "blades" of the former to allow zig-zag winding of some Litz wire someone gave me. Former was 3/32" phenolic laminate, cutting via a jig-saw. About 14 inches wide by 6 inches high. Q measured out to only about 120 at mid-band (using an old Booton Q Meter). Low enough distributed capacity but not near the Q claimed in the article, supposedly about 300. <shrug> Maybe ordinary cardboard would have worked better as the former? :-)

If you have some RF source of known frequency at the AM BC band, you can get a fair handle on the Q by using a high series resistor between RF source and the L-C parallel-tuned circuit. Observe the voltage across the L-C tank and de-tune the RF source frequency to the 71% amplitude, note the two frequencies on each side of resonance and take their difference. That's the delta-F "Q bandwidth" that, when divided into peak resonance frequency, will get you the approximate Q. The high resistance source-to-tank should be around 100 KOhms or so (higher the better) at 1 MHz to avoid introducing too much error. That resistor forms a "quasi-constant-current" stimulus...not ideal but good enough for an approximation when observing the RF voltage across the L-C tank.

"Ours is not to reason why, ours is but to cut and try..." :-)

I believe these are just 2 different names for the same thing. Silver mica caps come in various cases, and those cases have varied over the decades, but they've always consisted of a mica wafer plated on each side.

I've never seen a manufacturer's catalog that made this distinction.

The little mica compression variables would be an exception, as those are not plated, but I suspect you're not asking about those.

> Q alone won't determine sensitivity.

Very true. In fact the opposite is usually the case when it comes to function. In a good hi-q xtal set one often has to sacrifice sensitivity for selectivity...and vice-versa. Tighter coupling=more sensitivity but less selectivity because of loading effects. If you want sensitivity, go outdoors and hang wire or add sound-powered headphones. If you want selectivity, tweak the ckt.

But still, by aiming for highest Q you at least have something to work with when trading off.

Crystal radios are somewhat like a house of mirrors. Changes at one end reflect at the other end of the ckt. The old razor-blade radio is an example of everything being done the worst way but it still works. As you improve on the scheme each component becomes more and more critical.

Oh, no. Not at all true. Before about say 1940, mica caps were truly a sandwich of simple alternating metal plates and mica insulators. About 1950-ish they began 'plating' the mica.
Silvering is a mixed blessing. Many of the original silvered-mica caps now exhibit migration (leakage) problems.
It doesn't go without noting that in the 50s mica caps were not at all en vogue. Precision caps went thru an era where the ceramic (silvered) dogbone style were the most common.

Nowadays, I'm not sure exactly what it is I'm buying when I buy the "dipped mica" caps. I'm confident to say they are better than the old-timers but are they silver plated onto mica or what?

Thanks for the answers.
I have one TCXO 40Mhz 1Vp-p 10K//15pf Clipped Sine Wave.
My idea is of:
1) to gain 40Mhz Sine Wave through buffer with resonant circuit come
to an agreement for 2nd the IF (40.455)
2) to gain 20Mhz with a divisor x2 for the 16F877
3) ..and last.. to gain before 120Mhz (40x3) and then 480Mhz with
helical filter for clock the AD9954.
Thoughts are possible? It is one bad solutions??
Thank you again.

Yes, there is a difference and catalogs should say "silver mica" and if they don't then they are not silver mica. Today's sales people may not be techie literate and so today's catalogs may be less accurate. Silver micas were a little more expensive, too.

Besides a higher price, the overall performance specs were better besides haveing lower losses and better accuracy. Most of the time, silver micas were meant for free-running VFO circuits (IIRC) because you wanted thermal stability and as little losses to lead to heat which would cause drift.

However, if you wanted to be clever, you would get a set of negative temperature coefficient capacitors and use them to balance out the (all the rest of them) positive temperature coefficient capacitors and thus arive at a very low warm-up drift free running VFO.

I'm from the old days. Today, its all phase-locked-loop VFOs and "throw away" rigs when they break (nobody fixes stuff anymore [pardon my exageration]).

1. Air core coils will be cheaper, lighter in weight, easier to make.

> Easy of calculations?

2. Definitely.

> I assume you can get higher performance from ferrite coils than
> air-core coils, right?

You don't need as much ampere-turns to get a given amount of inductance
and thus, ohmic resistance will be less, therefore higher Q (in theory).

caveat: the magnetizable material you use for the core (i.e. iron,
ferrite, and other stuff that I think other guys here surely know better
than I) will have a big effect on useable frequency on up to some cut-off
threshold that may be sharp or spread out. Pure solid sheet iron, for
example, might be good at audio frequencies and maybe up to x00,000 Hertz,
but you need powdered iron to go into the megacycle range. There are other
core substances that get you up higher. Anyone else care to add to this?

Don't forget that winding a torroidal coil is not so easy. Some cores are
available in halves so you can make "pies", otherwise the "bobbin"
carrying the wire has to pass through the hole of the doughnut many times.

Most crystal radio builders go with air core coils...partly because
thats the way it has been always done and such plans are available and
thats the way its supposed to 'look' :)
And you CAN make a better Q air coil than what is attainable with
ferrite.

When I say unpredictable about the toroids, the calculated
turns/inductance comes out the same but not the Q. I've wound the same
coil on half-dozen 'exact same' ferrite cores and gotten Q ranging from
below 200 to nearly 400. Those numbers (in my set) cover the range of
not-so-good to pretty-darn-good. I'm not sure why that is other than
its not something intended to be. You won't readily find Q charts for
ferrites like you do for iron powder cores. As a consequence of this
you don't have any guarantee that the cores you get are going to make it
to the p-d-g range.

There's some advantages and disadvantages with using ferrite cores. The
size is the most obvious advantage. Among other advantages - they are
not affected by nearby components and do not pickup signals from the air
(self-shielding). Thats why I got started with them...I have a 5kw BCB
tower about 1600 feet from my QTH! With air core coils the band is
totally swamped.

On the negative side...the ultimate Q-limitation seems to be about 400,
inability to have variable loose-coupling to traps and other stages are
most notable. They also don't have the "looks cool" factor like a big
coil :)

Now back down to earth. A random ferrite core inductor is going have a MUCH higher Q than the average coil wrapped around a toilet tissue tube. You're lucky to get 80-100 with that type of coil. It may not play out as being important in a very simple circuit that has other shortcomings but as mentioned before it also helps to have a high starting point on as many of the components as possible.

Anyhow...its something else to tinker with!

-Bill

A typical medium-sized ferrite toroid coil for BCB use, FT-82-61 for instance, costs about US$1 and can't weigh more than an ounce and uses up about 4-5 feet of wire.

>
>> Easy of calculations?
>
>

Different calculation but one is as easy as the other. Just look for an online calculator :)

> else care to add to this?

True. There are two main substances used in ferrite toroids - and I can't quote either name - and they have vastly different permeability characteristics. I think the CWS-Bytemark website goes into some of these details.

> Don't forget that winding a torroidal coil is not so easy. Some cores

I've been referring to the simple doughnut cores. A BCB coil takes around 50 turns on -61 material. Even with my fat fingers it only takes about 10 minutes.

Am I correct in understanding that TSP, also called Sugar Soap (the stuff used by many to wash walls before painting) is essentially mostly lye? If so that is quite a cheap source you might want to consider.

Nope. TSP is Tri-sodium phosphate. "TSP substitute" is apparently
often composed largely of sodium carbonate ("washing soda" or "soda ash").

I believe that both of these chemicals will attack aluminum, but that
the reactions are a lot slower than is the case with lye (sodium
hydroxide).

TSP is Tri-Sodium Phosphate; lye is Sodium Hydroxide. They're different
compounds with different properties.

Sodium Hydroxide is incredibly nasty if mishandled: the human body does not
handle strong bases well, and Sodium Hydroxide eats flesh with terrible
avidity. It's really, really easy to lose meat or an eye to a drop or three
in the wrong place. I wear long gloves, a plastic apron, a long-sleeved
shirt, goggles _and_ a face shield whenever I have to work with it.

TSP, while much less nasty, is still nothing to play with. Google for the
Material Safety Datasheets (MSDS) on both.

It all sounds possible to me. It is not very different from some of the schemes we use commercially to generate internal frequencies (in spectral analysis equipment). Your idea of good filtering at 480MHz (and also, I hope, at 120MHz) is a good one, to keep out other combinations of multiplication. The one other thing I would be careful about is the phase noise of the oscillator. The AD9954 should be capable of very good phase noise performance, but you MUST feed it a clean reference to keep the output clean. I have recently tested some TCXOs which are very stable and accurate, but whose phase noise is not as good as I would really like. It is important to feed the oscillator from a very clean supply, but that alone is not a guarantee of good phase noise. See http://www.techlib.com/electronics/finesse.html for a nice idea to make a very clean supply for circuits that draw essentially constant current.

Cheers,
Tom

Hi All,

I am looking for a simple schematic to build a HF amp with a single 3-500z tube.
The reason for only one tube, as I only have one socket, however I do have a couple of used tubes.

I don't need a lot of power, but as much as I could from the single application.

If someone has a schematic around, that they would be willing to e-mail me, I'd be grateful.

Regards

Kevin, ZL1KFM.

Hi Tom,
Thanks for the councils. An alternative could be an oscillator (480 Mhz)
with 1/4 coax resonator and IC
PLL TSA5511 I2C Bus clocked by 40Mhz/10 (4mhz)...
I must think to us...

Ciao IK6GQC Rocco

Hi.

I have a question... I want to design an antialiasing filter and later
do an A/D conversion (undersamplig).

The signal (at IF) is at 44MHz and the bandwidth is 1MHz. How can I
design the antialiasing filter for undersampling with that information
?

Thanks

Hernán Sánchez

Hi Rocco,

I would use the multiplication. Within the loop bandwidth of the PLL, the phase noise will be determined by the crystal oscillator used as a reference PLUS the noise contributed by the PLL chip itself (the phase comparator and loop filter/amplifier), and outside the loop bandwidth, it will be determined by the VCO used in the PLL. The important thing, whether you use a PLL or multiplication, is to start with a reference which has low phase noise. In fact, your TCXO may have good phase noise...I don't know...I only know that some I've tested have not been as clean as I'd like. But I'm also setting pretty high standards for what I'm doing.

If I were in your shoes, I would build the multiplier system just as you first described, and use the TCXO you have, and if it proves to be too noisy (phase noise), then look for a better oscillator. If you can make even a crude measurement of the oscillator's phase noise before you start, that would be good, too, just to know where you are starting. My comment in my earlier posting was just to make you aware to look at phase noise, not to change the basic way you are going about it.

Cheers,
Tom

```
Slap a bandpass filter that's 1MHz wide at 44MHz around the signal input path.
Sample at something better than 2MHz (depending on how ideal your bandpass
filter is -- realistically you'll probably need to sample at 2.5MHz or
better... and things are simpler if you could manage to sample at 4MHz so that
44MHz ends up translated directly to DC rather than some offset).
```

>So what is in Draino?

The Draino brand drain-unclogger I have seen is a mixture of lye pellets, and granulated aluminum. When dumped into a drain and watered, the lye and aluminum react, generating hydrogen gas, quite a bit of heat, and often some steam. The heat helps break up the gunk clogging the drain.

"Red Devil" brand drain-unclogger is just lye, without the aluminum. If I recall correctly it even comes with instructions for making lye soap, using lye and fat.

Ah, so the voltage drop across the coil (due to the small internal resistance) and the close proximity of the wires give it some capacitance? Does this affect performance or just screw add unwanted capacitance?

Wouldn't adding space between wires cause some eddy currents and lower the L of the coil?

Does wire coating make a difference regarding the dielectric? Or is it another capacitance-altering effect?

Thanks again!
Dave

3349. Re: TCXO Clipped Sine Wave

Hi Tom,
my TCXO is GTXO-531 GOLLEDGE-UK product.

The parameters:
Clipped Sine Wave 1.0V p-p

Test Load 10k//10pF

Phase noise (@1.0Khz):
-135dbc/Hz max

To this point I have 2 possible ways:

1) TCXO+HelicalFilter480Mhz+BFR96 Buffer+HelicalFilter480Mhz

2) TCXO+Ampli-Multiplier x3(120 Mhz)+Ampli-Multiplier x4(480Mhz)+Helical
Filter480Mhz

Also here, perhaps it is the case to make some test.
But, to the first impact, what you tasks?

Hi Rocco,

The specified phase noise seems respectable to me. The ones I've been looking at have some very nice characteristics that I need, but phase noise about -115dBc/Hz at 1kHz offset.

Though it might look like more work, I would use (2). If I used (1), I would have a buffer amplifier from the oscillator, driving something to generate rich harmonics...since you need an even harmonic, use an assymetrical harmonic generator. Square waves, for example, have extremely low even-order harmonics ("theoretically" zero). But with (2), you can use a square wave to get the 3rd harmonic, and not have to filter much 2nd or 4th, since there is little of either of those in your square wave. A relatively simple filter at 120MHz will suffice. Then the 480MHz helical must attenuate only signals 120MHz away, not signals 40MHz away like in (1).

At least, that is my take on it. There are tradeoffs, always, and therefore you will see different designs to accomplish the same thing, and all will work.

Cheers,
Tom

Oh...be a little careful here! If you have a filter centered at 44MHz and 1MHz wide, even with perfect "brick wall" attenuation below 43.5 and above 44.5, it would be very bad to sample at 4MHz, or any frequency whose harmonic landed in the passband. That is because you will not be able to distinguish (with 4MHz sampling) between a signal in your IF at 44.1MHz or 43.9MHz. Both will come out aliased by the sampling to 0.1MHz.

For a more practical example, let's say you manage to find or build a filter with acceptable flatness from 43.5 to 44.5, and acceptable attenuation below 42.5 and above 45.5. (Acceptable means that whatever signals appear there will be attenuated enough to not cause trouble if they alias into the ADC's output in the desired 1MHz passband.) Then you can, at best, use a sampling frequency whose harmonic is at 43.0MHz, and whose sampling frequency is at large enough so that the sampling freq harmonic which lies on the other side of the IF filter passband won't let signals alias into the output passband. So maybe you could use 3.071429Mhz sampling, which has a harmonic at 43MHz, alisaing 43.5-44.5 down to 0.5-1.5, and the the next harmonic at 46.07MHz is more than 1.5MHz above upper frequency where the filter gives good enough attenuation to prevent aliases. (Good luck building a filter like that with acceptable performance from practical inductors and capacitors, unless you don't need much alias protection!)

If you have trouble seeing this, draw some pictures of what goes on in the frequency domain. Remember that you get nominally the same ADC response from a signal x kHz above the effective sampling rate (harmonic of the ADC sample rate) as you do from a signal x kHz below, and remember that you get response from signals x kHz away (above or below) the 11th harmonic just the same as the 10th harmonic or the 12th harmonic, with perfect sampling. So, do NOT let in frequencies that would let you see the same response from two different inputs...be sure to filter out those freqs that would give you the same response. (That applies to noise, too...don't let multiple copies of amplifier noise alias all down to the ADC output.)

Yes, you WILL end up with your desired passband aliased to something like 0.5MHz to 1.5MHz. But you can do whatever you want to that with digital signal processing. (You can also do I and Q sampling [quadrature sampling] just like you can do I and Q mixing, but you'll have the same problems with sideband rejection degraded by imperfect quadrature phase and amplitude matching.)

Cheers,
Tom

The internal capacitance of the turns isn't enough to radically change
the basic LC resonance. Instead it tends to result more like dielectric
leakage
>
> Wouldn't adding space between wires cause some eddy currents and lower
> the L of the coil?

Again, not significantly in the BCB example. Take for instance, a 4"
diameter coil wound with #18 wire, however many turns it takes. Lets
say 60. Winding the coil close-spaced as opposed to about
one-wire-diameter spacing will require a few less turns (maybe 10%) to
get the same L. But the close spacing WILL result in lower Q once you
re-establish the same inductance. There can be more than one reason for
this...is it the winding spacing or the length/diameter ratio or more
dielectric loss that causes this? (Its certainly not the R). Its
impossible to say because you can't have one without the other!

Smaller coils, say toilet-paper tube size, don't exhibit this effect -
or at least not to the same degree. But there's a whole different
geometry there and its not optimum.

Nobody really knows exactly what goes on here other than trial-and-error
experiments to see how they behave.

>
> Does wire coating make a difference regarding the dielectric? Or is it
> another capacitance-altering effect?

Yes it does. One of the tests on a good high Q coil is to set it up on a Q-meter then touch a piece of your coil-form material (or wire-insulation) to the coil and see how it behaves on the Q-meter. It shouldn't move. Lossy core material/insulation will cause a visible effect with this test. I'll reiterate in case someone jumps in and reads this without reading the earlier parts of the thread...you won't see this happen with a low-q coil but as you get higher in Q it becomes more and more evident. In fact, with a big solenoid coil and Q>500 you pretty much have to tie the sample material onto the end of a stick to do this test because of hand effects. Not to be confused with resonance detuning effects.

There's no good rule of thumb for insulated wire other than a test like this. There's quite a bit of insulation material in 660-strand litz and thats darn good wire. No way to make a comparison because BARE litz can't exist! I don't think I've ever heard a comparison made between say bare 16-18 wire vs enamelled. I tend to think any difference would approach the 'too difficult to evaluate' range.

It took me awhile to figure out what waterslide decals were---then I
remembered! The last time I used them was many decades ago on model
airplanes.

What a great idea... the possiblities are endless. A Google search for
'waterslide decals' came up with many hits.

Oooops. Correction. That 3.07MHz sampling frequency will NOT work for the example filter I gave, because the harmonic at 46.07 will alias the range from 45.57 to 44.57 into the 0.5-1.5MHz output band. And 44.57 to 45.5 does not have acceptable attenuation. Better use instead a 4.3MHz sampling, so that the 10th harmonic converts the desired band to 0.5-1.5MHz, and the 11th harmonic at 47.3 converts the highest unprotected frequency, 46.5MHz, to 1.8MHz, which is above the output band of interest.

Cheers,
Tom

Seems to me that 256 or 512 is reasonable. Then decide how many kHz/rev you want, and that tells you the step size. If you want 10kHz/rev, 512 steps would give you just under 20Hz/step, which seems reasonable to me. I wouldn't want it any coarser than that, and I'd actually prefer finer. Processors are very cheap; you can easily process the quadrature step info up to dozens of revolutions per second. If you budget ten instruction cycles to process each step, and you're using a slow processor at 1usec/instruction cycle, you can process 100,000 steps a second, if the processor has nothing else to do. You can process 10,000 steps a second, or 200kHz/second, with just ten percent of the processor's time. A nice "plus" is to accelerate the tuning when the steps come fast, so you might bump the tuning up to higher Hz/step as the steps come faster. Expect to spend some time on the algorithm to get a smooth "feel" to it, though. The accelerated tuning when the knob is turned more quickly is a feature commonly found in test instruments. I haven't ever had a problem with the HP/Agilent encoders with respect to the output looking like "noise." The outputs are very clean digital signals with no "bounce" if you're turning in one direction.

Cheers,
Tom

PS...Tim, did you find an encoder yet? Drop me an email if not...

The discussions in this thread make me wonder... it seems like the tough part of making variable caps in the "classical" shape is making the plates. In my distant past, I was involved in making modest quantities of punched aluminum parts, and found a shop that was willing to make a punch/die set for the parts, even though my initial order was for only a couple hundred of them. (Eventually I ordered enough to wear out the punch/die set and they made another one...probably did 10,000 or so total.) Once you pay for the punch/die, the parts become pretty cheap, and the uniformity is vastly superior to what you could reasonably do by hand. So, the question becomes, if the plates (rotors and stators) were available in maybe two or three different basic sizes, how many frustrated hams would be interested in buying them? Might it be enough to make the punch economical? Would you be willing to pay, say, two dollars per plate for 0.0625" thick plates with 3" rotor diameter? A set of 25 such plates, using 0.1" gap (good for maybe 7kV peak?--provided the edges are properly rounded), would give you about 190pF. Do the people who would be trying to build such things already have the ability to do the rest of the parts, or would they need to be included too? Does someone already sell kits of capacitor parts?

That's obviously way beyond what the OP needs for a receiving loop, of course! For that, I'd probably use a varactor diode...or find a radio receiver to scrap one out of if I wanted to stay mechanical.

Cheers,
Tom

For short runs today laser cutting would be better -- the programming
and setup costs are much lower than tooling. The quality will approach
that of a good die set and exceed that of a poor one. There will be a
point where things'll be cheaper to punch out with a die set, but it'd
probably be in the thousands if not tens of thousands of plates.

I wouldn't use a varactor to tune a recieving loop because of intermod.
Antique Radio Supply and others have various variable caps for sale.

Thanks again for the reply.

>From what I've read here and elsewhere, I'm debating either making a spider coil or a tight wound 4" cylinder (about 1" length). Is there any significant advantage to either?

I can see with a powered ferrite core how the spacing would make less of a difference... but if tight winding results in a lower Q/other effects, why space the windings for air-core, crystal radio coils, period?

Thanks!
Dave

Good point about other tooling methods (laser cutting not the only one available), but the question remains, how many people would actually be interested in buying plates, at what cost levels? (At the time I was making the other parts, soft tooling was cheaper for very short runs, but the shop that did the punch/die was set up to make such tools at very low cost and easily beat the soft tooling for modest runs. You just need to decide how many of your parts you want, and go shopping.)

As for using varactors on receivers loops, if you use back-to-back diodes and don't have to deal with seriously big signals, distortion should be at worst a very minor problem. For a fairly high Q tuned antenna, the signal voltage across the diodes for signals you're not tuned to is pretty small. Of course, the reason it's so hard to find small (receiving size) mechanical caps now is that their job has been taken over...by varactors.

Cheers,
Tom

This would be a good emachineshop.com order. You can choose any of the processes that people are discussing on this thread, depending on the expected volume. When I played with their estimating software, my experience was that pretty much everything cost roughly:

$100/ea in qty 1 => $100
$11/ea qty 10 => $110
$1.20/ea qty 100 => $120
$0.13/ea qty 1000 => $130

etc. I figured the biggest risk in using them would be the temptation to get 10x more units for 10% more and then have a zillion whatevers (eg rotor plates :) around the garage. I've been trying to think of a project that needs 100 identical widgets, and a homemade air variable might be it.

At the price you suggested (a couple of dollars per plate), the cost
of putting together a good-sized air variable is going to be fairly
fierce. It may be somewhat less than the cost of a new, commercially
manufactured AVC, but it's probably not competitive with the cost of
used-but-serviceable air variables at hamfest/fleamarket prices. You
might find that it was appealing only to those who needed a fairly
specific size/capacitance/standoff-voltage combination, not available
used.

You might find it attractive to specialize a bit. One not-uncommon
application for large air variable caps these days, is people who want
to make a magnetic-loop transmitting antenna. In this application,
keeping resistive losses in the cap to a minimum is very desirable
to help keep the Q and efficiency as not-terribly-low as possible.

One way to do this is to use a welded rotor/shaft assembly, and welded
stator plates, to reduce resistive losses. This is beyond the
capabilities of most homebrewers, I think. An alternative is to use a
soldered construction, which can't be done easily with aluminum but
which is relatively easy if your shaft and spacers are brass, and the
plates are either brass, or PC-board material (double-sided would work
best).

Hence, you might increase the demand for such stamped or laser-cut
plates if you were able to offer them in materials other than
aluminum. The materials cost for brass would probably be higher than
for aluminum, but you might be able to offer plates in double-sided
FR4 for prices no more than aluminum.

Huh? You wrote, "if tight winding results in a lower Q/other effects, why space the windings for air-core, crystal radio coils, period?" Do you not want a higher Q? Generally, people try for the highest unloaded Q they can get, under some set of constraints.

Close spacing lowers the Q mainly because the current in the wire is no longer radially symmetrical, if you look at a cross-section of the (round) wire. That raises the RF resistance of the wire. For decent (low-loss) form material, it's mainly the RF resistance of the wire that determines the loss and therefore the Q. Generally, highest Q for a given diameter and length is obtained by spacing the wire about two wire diameters, center to center, at least for high frequency work. If you want to use Litz wire, there's an optimum stranding...more, finer strands are not necessarily better as you get to either lower or higher frequencies. You should be able to find info on that, if you do some searching.

There is such a thing as TOO HIGH a loaded Q. Let's say you start off with a coil with unloaded Q of 500, and couple lightly to it with your circuit (antenna and detector), so the loaded Q is 250. That means the bandwidth at 3dB points, if you tune a station at 1MHz, is 4000Hz. If you've tuned to the center of the station, your demodulated bandwidth will be only 2kHz. Since the rolloff is gradual with a single-tuned circuit, voice should be OK, but you'll be missing out on a lot of the highs. (Mind you, it's not easy at all to get an unloaded Q of 500 at 1MHz!)

Using a very hack crystal radio--coil of about 3" diameter, antenna just ten feet or so of wire, and an HP zero-bias schottky detector diode--but into a low-noise audio amplifier--I've been able to listen to standard broadcast stations a thousand miles away in the evening. Biggest problem is getting rid of local stations...I'd use probably a carefully designed three-resonator filter and a much better wire antenna if I was serious about it.

Cheers,
Tom

Cool, Ben. Thanks. I'm wondering what part you put in to get 13 cents each at 1000 parts. That would be very attractive, but I keep getting over a dollar a plate for 3" diameter semicircles with a tab/hole for the shaft, for rotor plates. Admittedly, the 0.063" aluminum thickness is more than needed for many applications, but dropping it to 0.024" doesn't help a lot. I don't figure that making your own cap for low power applications is going to be very attractive, so I'm figuring the larger sizes. Also, what machining technique did you pick?

Cheers,
Tom

At two bucks a pop for plates you _ought_ to be burning up most of your

money in setup, tooling and handling, with very little going to the actual material.

Hence brass shouldn't be too much more expensive.

I might be more interested in a kit that would let me saw plates out of FR4 and assemble a precision cap -- so if you supplied frame & shaft pieces that would accept .031 or .062 FR4 that would be a cool thing.

Thanks for the information! Is there an advantage to wrapping cylinder
coils as opposed to spider or torroid, other than ease of construction?
I'm debating which one I'd likely get the best result with... I'll
probably make both to try it out, but I'd like to know which one would
'probably' work best.

Thanks again,
Dave

3373. Linear amplifier input mathcing circuit

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-20 22:45:48 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <wuADe.74296$G8.64787@text.news.blueyonder.co.uk>
Source record: 18054

I bought a heatsink/PCB containing two RF transistors (2N6080, 2N6083) at a radio rally. I'm not sure what frequency it was for but it looks like a 2m or possibly a 70cm amplifier. It appears to be from the back end of some rig. It has antenna switching relay and decoupling and RF loads on the collectors. I intend to re-use it to make a 20W linear for 4m. I have stripped off all the matching parts between the stages (trimmers, Ls and surface mount type Cs). When I tested the transistors with a multimeter I was relieved to see that the BE and BC diodes gave a good reading which suggests that the transistors are intact.

I have been reading a lot about linear amplifiers and matching circuits from the usual authors in RSGB and ARRL books. I am slowly getting an understanding of what is going on. I also have a Motorola databook which gives the datasheet for the two devices.

The databook shows that the input is capacitive below 180MHz and down to 130MHz (3.18-j4.3). Extending the line on the smith chart it appears that the input gets more capacitive at 70MHz. My understanding was that a capacitive input would be counter-acted using a series inductor, however the original amplifier clearly had a capacitor from base to ground. In PW April 96 I stumbled across a 50MHz linear amplifier based on a 2N6080 and 2N6082 combo (TA6U2 from Spectrum Communications - which may still be available today). For both stages there is 1nF of capacitance from base to ground. In a third design for which I have the schematic a 2m amplifier using a 2N6080 as the first stage also has capacitance from base to ground. I'm puzzled.

Anyway I constructed a T type input match using 200pF trimmers and a 3 turn coil rescued from the original circuit: C from i/p to common, C from common to gnd, L from common to transistor base. I read somewhere that this was called a "sloppy match". Using a MFJ259B as a signal generator I can adjust the trimmers to get a match at both 50MHz or 70MHz. Interestingly adjusting from the centre frequency the bandwidth of SWR less than 1.1 is greater at 50MHz than 70MHz. I'm guessing that this match circuit has multiple solutions for a fixed L depending upon Q, and that Q is lower at 50MHz.

I understood that the L in my match would combine with the L of the transistor input impedance which would just result in a bigger overall L in the match circuit. Certainly this circuit appears to work.

->So why in three seperate designs do I see large capacitance between the base of the transistor and ground?

Using the usual formula Zout=(Vcc*Vcc)/(2*Po)=(13*13)/(2*4)=21 I have added a 100nF and 22ohm resistor in series from the collector to ground to give what I hope is a sensible load (to test out the circuit). This will later be replaced with another match circuit, which I assume will need to match from 20ohm

instead of 50ohm (as needed for the first stage). When experimenting without the proper match circuit do you even need a load, or is my idea sensible?

regards...

That was just an example. I just made a quick 3" diameter rotor with
center hole, laser cut from 6061T6 .047 and 1 is $103, 10 are $123,
100 are $264. It's not quite as steep a curve as the other parts I was
playing with. Since that's laser cutting you can group parts, so if I
throw on a stator too it only goes up to $404 for 100. If I go to slightly
thinner mild steel it's $254 for 100 pairs. Not sure how much difference
Al vs steel makes for this application.

I bet the turret punch would be cheaper, but it can't make the convex
curves.

If you make a die for the rotor it looks like the tooling is about $1k
but the per-part cost can go down to 15 cents each at quantity 10k (for
a net price of about 27 cents each). On the other hand, the lead time
is 72 days!

3375. coupling loop for loop antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-21 00:31:59 UTC

Source record: 18058

i see two different designs on the net for receiving loops. one is to wind the pickup loop with the main loop, and another is to use a 1/5 size loop off center at the bottom. what are the pros and cons for each setup? what benefit is there to a pickup winding as opposed to just inductive coupling to the internal loopstick by proximity?

They're going to be very similar in performance. If you do the solenoid (cylinder), go with one wire spacing between turns instead of tight wound. Thats been pretty well proven to give a bit better Q. And 16-18 ga wire is also in the 'best' range for both the spider-web and solenoid. Next step up would be some serious litz wire.

>
> I can see with a powered ferrite core how the spacing would make less

> effects, why space the windings for air-core, crystal radio coils,
> period?

I'm not 100% sure I understand the question....On a rook/basketweave/spider coil there's inherent spacing already. And a solenoid coil will also do better that way...on larger coils. The way I understand it is that there are several factors at work - primarily interwinding capacitance and overall l/d ratio. In practice, as you change one you also change the other. You can compensate one for the other somewhat with a different diameter coil, different gauge wire, etc but the general concensus is that 4"/16-18 wire/~1 wire diameter spacing is pretty close to the best you can squeeze out of that class of coil.

HTH.

I s'pose Reg, the local expert on proximity effect, etc., should pop in here and 'splain it all. Seems, though, like it's wrapped up in practicalities. For low-frequency work you typically want a lot of inductance, so you use fine wire so you can get a lot of turns in a relatively small volume. The wire diameter is small enough that, at low frequencies, the skin depth is large compared with the wire size. I believe you will then find that the proximity effect won't have as much influence on the Q as in the case where the skin depth is a small fraction of the wire diameter. So for a 50Hz/60Hz power transformer, you won't find the turns spaced apart any more than needed for insulation.

You can do a Google search for <conductor proximity effect> and find a bunch of references. The stuff at http://www.national.com/nationaledge/nov04/adc_article.html has some nice pix to show the effect in a bit different environment than we're talking about here.

The Q you actually obtain may depend on so many other things than just the shape of the windings that it's not possible to tell you the "best" geometry. But I can tell you that if you make a large coil of good design, you should be able to get to a high enough unloaded Q that doing better with a different geometry about the same size will give you only small returns on the performance in the circuit. That is, if you do manage to make a solenoid coil say 5 inches long and 5 inches diameter, maybe getting the Q up near 500 if you're careful, then operating it at a loaded Q of 100 (for a 10kHz bandwidth at 1MHz), the loss in the coil compared with an INFINITE unloaded Q is so small as to be nearly unnoticable. If my mental arithmetic is right, it would be about a 1dB difference, just barely audible. And of course, you won't get anything like that much improvement in Q with a different shape. Plus--the standard solenoid shape is easy to construct! (There ARE reasons for wanting higher unloaded Q, if you want to operate at a higher loaded Q and if you want to build a multiple-resonator tuner, but my impression is you are not there yet!)

Cheers,
Tom

Me again...I should have read the later threads before my earlier reply.

Tom is correct about the Q using litz. Some guys have tried 48 ga litz and said it nosedived in performance from the more-common 46 ga litz. I've seen that explained with a critique of skin depth in that the rf resistance of 48 is considerably higher at those freqs. Strand count seems to still be in the 'more-is-better' range at BCB. 660-strand is commonly used in DX sets...although I haven't graduated to that level of expenditure myself :)

As to which to try....in a single-tuned set you won't notice the difference. If you have a strong local BCB station the toroid will do a very effective job of decreasing direct pickup by the coil. You might still want a trap inline, though. Guess which type of coil makes the best trap in this scenario!

My own tests gave a slight nod to the spider web coil. Not enough to be noticeable in reception but enough for "spec-talk". The spider-web is also less prone to proximity effects and even direct pickup because it is 'directional'.

My own dx set which is admittedly tailored for my particular environment uses a toroid on the first tuned stage, a toroid inline trap, then a spiderweb on the detector stage with a loose coupled trap made with a loopstick ferrite. A little of each, huh? I can receive stations within 80-100 kc of the 5kw local that is 1/4 mile away on 1370.

My best recommendation would be to seriously consider a double-tuned set. Its a whole different world than a single-tuned one.

Probably more than anything else the preference would be determined by
what type of radio you're coupling to.

Fer instance...a set with a built-in antenna and no external ant
connection would HAVE TO be done by proximity...or else winding a
coupling loop onto the built-in antenna :)

A set with external antenna connections only often has no internal ant
to couple to.

There's shades of grey between those two but thats the basic pro/con.

==========

The coupling and main loops behave as the primary and secondary
windings on an impedance matching transformer.

The number of turns is fixed at 1 to 1. So the impedance matching is
done by using different loop diameters.

The 1/5 diameter coupling loop matches the antenna to a 50 ohm
receiver or transmitter.

The large diameter coupling loop matches the antenna to a high
impedance receiver such as 1000 ohms.

Theoretically, the impedance matching ratio is equal to the square of
the loop diameter ratio. The receiver input impedance is usually
known. The trouble is to find the impedance of the loop antenna. But
it is not a critical matter.

3383. Software tool for XTAL checks: xtalfind 2.0

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-21 09:52:22 UTC
From: PaoloC <ollollo@hotpop.com>
Message-ID: <42df7002$1_2@x-privat.org>
Source record: 18064

Hi,
I am glad to inform you that I have updated my 'xtalfind' program to
include tests for software defined DC receivers and DRM converters.

xtalfind is a Perl script that, given a (list of) XTAL frequency,
returns all its possible uses for HAM applications, (sub)harmonics
included. Currently xtalfind checks for the following matches:

* DC RX or TX (HAM bands)
* RX with 455kHz IF (HAM bands)
* RX with 10MHz IF (HAM bands)
* RX with 12kHz IF (HAM bands)
* RX with custom IF (HAM bands)
* SDR LO=4*F (HAM bands)
* DRM converter 455-12kHz
* DRM converter 9011-12kHz (ICOMs)
* DRM DC RX for known DRM broadcasts

You can see a sample output from a previous release at
http://spazioinwind.libero.it/ik1zyw/hardware/myxtals

You can download the software from
http://spazioinwind.libero.it/ik1zyw/software/xtalfind-2.0.tar.gz

The Perl interpreter is available for most operating systems, so
xtalfind should run almost anywhere.

Don't throw a XTAL before asking xtalfind! :-)
Never underestimate the power of weird frequency XTALs! ;-)

>(TA6U2 from Spectrum Communications - which may still be available today). For
>both stages there is 1nF of capacitance from base to ground. In a third design
>for which I have the schematic a 2m amplifier using a 2N6080 as the first
>stage also has capacitance from base to ground. I'm puzzled.

>->So why in three seperate designs do I see large capacitance between the base
>of the transistor and ground?

I don't think you have considered the low value of 'R' being
dealt with here. Translating 3.18-j4.3 @ 130MHz into a parallel
combo gives 8.99ohms||185pF (according to Agilent's AppCAD). Now
with pi-tank matching (possibly not the optimum method), you would
need a shunt capacitance of Xc = R/Q = 681pF using an arbitrary Q
of 5. So a capacitor of 497pF (half your 1nF) together with the
184pF of the device would do nicely.

Cheers - Joe

3385. Anderson 'Powerpole' Connectors

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-21 13:42:06 UTC

Source record: 18068

After hurricane Charley passed overhead (official track had it passing directly overhead of my house) blowing off roofs and downing powerlines---we were out of power for a week, I decided to review my emgergency equipment capabilites. After extensive Internet study I learned that the power connectors of choice, endorsed as standards by the ARRL, ARES and RACES for emergency hookups are the Anderson 'Powerpole' connectors. Using the same connector body but different internals parts provided a connector with current capability up to 45 amps. The concept of a 'genderless' connector was also mentioned. I purchased a large quantity of the 15, 30 and 45 amp connectors along with the special crimping tool and began to exchange all my old connectors with the new 'Powerpole' connectors.

When I first got the 'Powerpole' connectors about a year ago and played with them something odd about them caught my attention but I could not explain why. A couple of days ago while making connections I discovered that the 'genderless' capabilities of the connector allowed them to be connected side-to-side, in otherwords, red-to-black, or black-to-red. The possibility of making a direct short to ground---especially from an automotive battery exists (grounded chassis/negative ground)! Using the 'Powerpole' connectors makes it imperative that fuses be inserted inline, not only with the battery positive terminal as is common practice, but ideally with both sides of the power leads on the equipment side.

The connectors I used in the past and standardized on were the Amphenol two pin connectors. The ones with the wide and narrow blade. The female went to power source, and male to the equipment; furthermore, the cable clamp, that the 'Powerpole' connector do not have, kept the connecting wires from being pulled out or broken from repeated flexing. The Amphenol connectors were not only a gendered connector but could only be coupled one way---avoiding the problem of the 'Powerpole' connector.

I won't change back to the Amphenol connectors; I'll stay with the 'Powerpole' connectors, but it sure makes them an awkward solution and 'Hammy' way of doing things that require a bit of care when using them---especially under emergency conditions.

I'm looking to buy in kit form (or prebuilt if it's cheap enough) a receiver whose sole purpose in life would be to sit on 10.151 LSB and decode APRS packets to be relayed into APRS-IS on the internet via a computer with a sound card. I've been looking around and I've found the 30 meter half watt Rock-Mite CW tranceiver from Small Wonder Labs for $27 including shipping, $39.50 with the connectors. I'd imagine this would work just fine if I swapped the crystal in it to 10.148.5 or so, but I really don't need the transmit option, unless there was some way to modify it to take the sound card output from my computer and transmit 300 baud packet with it. It looks like since you can choose two frequencies 1khz from each other, that maybe it would be able to be modified to transmit the frequencies for mark and space and perhaps be switched by some sort of FSK mechanism controlled by a serial port. Anyways, that's more than I think I want to get into with this project and would be happy if somewhere out there was an easy crystal controlled kit that will just receive one 30 meter frequency in lower side band.

Thanks

3387. CW filter/notch filter

Newsgroup: rec.radio.amateur.homebrew

From: Samuel Hunt <shunt010@hotmail.com>
Message-ID: <dbolpj$3ij$1@nwrdmz01.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 18070

I'm looking for a circuit design to a CW filter centred around 1khz that's about 200hz wide and then rolls off very rapidly.

I'm planning to build a AFC system for SSB, which has a 1khz pilot tone that will be used to lock the frequency correct.

I then need a circuit with quite a tight notch around 1khz to kill off the pilot tone once it's been locked on, so you don't have an annoying whistle on the reciever.

Can anyone possibly help with any circuit designs or where I can find some????

I've had a look at a twin tee filter, but I'm not familiar with this design. Would this be suitable, is it worth me reading more about it and learning, then using this?

Thanks all,

Sam

True 'nuff. If you do this, and also have a secondary ground path
present (e.g. through the antenna system), bad things could occur.

The chances of this can be reduced by:

- Not trying to plug 'em together by touch alone.

- Pick a standard orientation (most ARES groups have standardized on
a "Red on the right, when looking into the connector, contact
tongues are on the top" orientation).

- Assemble the connectors in advance of need.

- Secure the red and black connectors together after slip-fitting them,
so that they can't come apart and be reconnected incorrectly.
Anderson provides "roll pins" for this purpose, to lock 'em
together, but I've heard some people say that these can vibrate out
of the connectors. I prefer to use a drop of Crazy Glue or acetone
to permanently bond 'em together.

> The possibility
>of making a direct short to ground---especially from an automotive battery

Good advice!

Whenever I build equipment for 12-volt plug-in use, I prefer to stick
a reverse-polarity diode across the line, right after the equipment's
main 12-volt fuse. During normal operation there's no current flow in
the diode and no voltage drop (unlike what a forward-biased diode in
series with the line would cause). If the equipment is accidentally
hooked up with polarity reversed, the diode clamps the reverse voltage
and the fuse blows instantly, almost entirely eliminating the risk of
damage to the equipment.

>I won't change back to the Amphenol connectors; I'll stay with the

You raise a valid point. I have yet to hear of this actually
happening in practice, but it's certainly possible.

I'm told that the underwater-diving industry has been using PowerPole
connectors for years - a local diver who became a ham last year was
overjoyed to finally learn how and where to get "diving light"
connectors at a reasonable (non-dive-shop) price. I'll have to ask
him whether he knows of any such accidental-reverse-hookup problems in
that industry.

Very nicely done...

I toyed with the idea of designing a couple of flat dies to punch out the stator and rotor plates and market my own series of capacitors. I agree, the high price of those capacitors are unwarranted.

There was no need for two variables in that tuner... a single DIFFERENTIAL capacitor would do nicely and eliminate the extra adjustment during tune-up. For some unknown reason Hams still need a tuner with two capacitors---it was nice to see MFJ offer the Differential-T tuner Model 986.

Many years ago (before the MFJ 986 tuner) as an experiment I built a field expedient tuner using a differential capacitor made from two telescoping cardboard tubes and aluminum foil (two plates outer and one plate inner tube) and slid the inner tube in and out to acheive an antenna match with a 28 microhenry tapped coil. It worked fine at 100 watts and many contacts were made with the end fed wire but dilectric heating of the cardboard tubes was observed.

[snip]

Thanks for the reply Dave. That's precisely the point I'm trying to make.
My connectors are oriented in the preferred ARES configruation and crazy
glued together but that doesn't mean anything. You can still can mate the
assembled connectors together side-to-side, red-to-black and black-to-red.

The only options of preventing this from happening are to carefully observe
the mating of the connectors and use fused leads to protect against shorts
resulting from misalignment.

I've found an excellent bandpass filter. It's 4 pole and is supposed to be a CW filter. When I tune it up, it works really nicely to pass about 250hz 3dB bandwidth, then has incredibly sharp edges so at 500hz BW, it's about 20dB down, and then just rolls off more. This is almost perfect for what I want.

Now the only thing is finding a tight notch filter that does similar, but the opposite, the tighter the better. Really I want to try to kill off my 1khz carrier, when it's no more than 50hz away, so it needs 100hz BW then be rolled off at about 200hz.

After I've got these circuits sorted, I might be ready to "trial" earlier than I originally thought.

3392. QUESTION: Homebrew Near Field 3Ghz Frequency Meter.

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-21 21:51:43 UTC
From: Timothy@tholtom.freeserve.co.uk
Message-ID: <1121982703.888190.178630@g14g2000cwa.googlegroups.com>
Source record: 18075

There are plenty of homebrew frequency meters on the market, basically amp, PIC and display. Problem is I haven't seen one yet that works above about 50Mhz. Does anyone know of a circuit diagram for something capable of about 3Ghz? Something like a homebrewed version of the Optoelectonics offerings.....

Thanks,

Tim

3393. QUESTION: Logarithmic Amplifiers and their Uses

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-21 21:55:32 UTC
From: Timothy@tholtom.freeserve.co.uk

Wow... it's more complicated that I thought.. So, what you are saying is that I must do "mixing" with all the harmonic frequencies, almost to the 11th harmonic to find the right frequency that don't generate a mixing signal (with the IF signal) at the 0 - 1MHz range ?

Thanks

Hernán Sánchez

Assuming that you have a bandpass filter that allows your desired band
to pass (say 43.5 to 44.5MHz), and that has enough attenuation outside
some band (say 42.5 to 45.5MHz) to protect against aliases, then the
only harmonics of the sampling frequency that are of interest are the
first one below the passband, and the first one above the passband.
That is assuming that you don't have a harmonic of the sampling
frequency inside the passband, which I explained would be bad because
you can't distinguish between a signal xx.xxkHz above that harmonic and
a signal xx.xxkHz below that harmonic.

You can list some specific rules. Try this:

Define four frequencies for your filter:
f1 = frequency below which attenuation is great
enough that you can ignore signals there.
f2 = bottom edge of the passband, where
attenuation is small enough that signals are OK.
f3 = top edge of the passband, like f2, so signals
between f2 and f3 are all OK
f4 = frequency above which attenuation is great
enough that you can ignore signals there.
So, f1<f2<f3<f4.
(in the example above, f1=42.5MHz, f2=43.5MHz, f3=44.5MHz and
f4=45.5MHz. But the passband does not have to be symmetrical; f4 could
have been 46.5MHz for example, and the equations below will still
work.)
Define the sampling frequency = fs
Then there are two possibilities that will work:
(1) a harmonic of fs, call it n*fs, falls below (f1+f2)/2,
and (n+1)*fs-f4 > f3-n*fs. In that case, the band
from f2 to f3 will be aliased down to the band
from f2-n*fs to f3-n*fs. In fact, each frequency
f in the passband will alias (mix) to f-n*fs.
OR
(2) (kind of the mirror image of (1)) a harmonic of
fs, call it m*fs, falls above (f3+f4)/2, and
m*fs-f2 < f1-(m-1)*fs. In that case, each
frequency f in the passband will alias to m*fs-f.
In other words, the output spectrum will be
flipped compared with the input: lower freqs
in the input spectrum will be at the higher end
of the output (digitized) spectrum.

In both (1) and (2), the first requirement as I've stated them is so
that nothing on the other side of the sampling harmonic from the

passband is big enough to cause trouble in the output frequency range. The second requirement insures that nothing aliased by the harmonic on the other side of the passband from the harmonic doing the work will cause trouble in the output passband. But beware: the digitized output may very well contain frequencies which lie outside the passband, because your analog filter on the passband does not cut them off sharply enough to get rid of them. You can use DSP algorithms (FIR or IIR filters, for example) to do a good job getting rid of the remainder that you might not want in the output.

Cheers,
Tom

(Sure hope I got all those inequalities right! I trust someone will double-check them and let us know if they are wrong...)

Generally frequencies that high are done using prescalers. It's also possible to do it with a mixer, and there are some other specialized techniques. Several companies make prescalers. They tend to be expensive and not very easy to find. An alternative way to do the prescaling is to use a PLL chip. Many of them (like the National PLLatinum series and the Analog Devices parts) have one output pin that can be programmed to monitor the divide-by-n chain output, and you can program the divide-by-n to give you some useful fairly large division, to get down to a frequency that's easy to count at that output pin. The PLL chips like that tend to be inexpensive and more readily available than the prescalers. So what if you're not using about 75% of what's in the chip? You may want to use an MMIC gain block between the signal input and the PLL or other prescaler to get the sensitivity up a bit.

Cheers,
Tom

A switched-capacitor (commutating) filter can put a potentially very sharp notch at a frequency determined by its clock. I assume in this AFC that you'll have access to the frequency you're trying to filter out. If you use an 8-capacitor version of the filter, you just need to clock it at 8* the freq you want to remove.

You CAN also design a continuous-time band-stop filter.

(Soap-box comment: seems like this would all be a lot easier if you just digitized the signal at 8k samples/second, making detection and removal of fs/8 pretty easy... or just transmit the SSB with a suppressed carrier that you don't have to worry about removing.)

Cheers,
Tom

I built one last year. I used a PIC16F628 and LCD display.
The HF input uses a 74F74 as a 1:4 prescaler and works up to
about 150MHz. The UHF input uses a Fujitsu 1:128 prescaler,
IIRC it is an MB510. The prescaler is rated for 2.7GHz. I have
used mine up to 1300MHz. The timebase is a very high quality
9MHz TCXO from Ericsson mobile phone equipment. It never
wanders more than 1Hz away from my 10MHz oven controlled
oscillator.

At HF, gate times are 400mS and 4S for 10Hz and 1Hz
resolution. At UHF the gate times are 1.28S and 12.8S
giving a resolution of 100Hz and 10Hz.

I don't have a schematic of the counter. Most of the
hardware design is stolen from my old display/stabiliser
circuit: http://www.eircom.net/~ei9gq/stab.html (from memory?).

The PIC and lower frequency circuitry is on Veroboard. The
VHF/UHF is built dead bug style on copper clad board.

From: Timo...@tholtom.freeserve.co.uk on Jul 21, 5:55 pm

>Anybody know of a site that explains what exactly a logarithmic
>amplifier is and how and where it is applied?

Not known by me. A logarithmic AMPLIFIER is a rare bird in
finished goods and the "successive detection" type is much
more common.

The best text I know of is "Logarithmic Video Amplifiers" by
Richard S. Hughes, then at the China Lake (CA) Naval Weapons
Center, Artech House 1971, published by Horizon House-Microwave,
Dedham, Massachusetts. "Video" in this context is up to 60
MHz plus...

Texas Instruments once made a Log Video Amplifier dual in a
dual-inline-package. Used that for some log-video R&D
circuitry in the 1970s. It went out of production, probably
due to low demand.

It's use was/is mainly in radar signal processing, considering
that the radar return varies a terrific number of db in
signal strength. One use that I had it for was to find the
3 db down point on an RF pulse which had a large peak signal
strength string. It is now used as a power output indicator
and, in Europe, has been the central part of a wide dynamic
range power meter for hams.

> I'm thinking in
>particular of the Analog Devices offerings.....

Those seem to be "successive detection log amplifiers." The
purpose there is to do a demodulation in amplitude of the
RF using successive non-linear amplifiers, each with its own
detector, the detector outputs summed. Summation of detector
outputs is a logarithmic characteristic compared to linear
input.

There IS a successive SUMMATION amplifier, or at least WAS,
and that does much the same although it sums the RF without
demodulation. Speaking from some experience, they are a
total #$%^!!!! to keep phase-stable over amplitude variations.
Others have found that. Not too many of those products were
available as ready goods.

Actually, if you want to be disgustingly cheap and easy (no machining required) then use a wheel mouse (complete) - plug it into your radio, and decode the wheel pulses for up/down = simple switch select and a few gates for tuning "rate". Worth a try - its not the space shuttle your trying to build.

Yes, the input signal will try to "mix" with ALL the harmonics of the
sampling frequency. You must pick the sampling frequency so that the
desired signals mix down to the output you want and also no other
signals that may be present can also mix down to the output you want.
That is where the anti-aliasing BANDPASS filter helps by restricting
the possible input signals.

Dave-

Anderson may supply the roll pins if you ask, but they don't come with the connectors.

I found out about the adoption by various emergency organizations such as RACES, and converted all of my equipment. I started with a roll pin in each pair, but soon noticed that over half of the pins had fallen out. Fortunately there was no damage from pins falling into live electronic equipment.

Thinking I just had the wrong roll pins, I tried to buy some from an Anderson dealer. That is where I heard about using Crazy Glue.

I hadn't considered offsetting the connectors so black and red could connect. Yes, that would be a problem, so don't to that!

Although Anderson Power Poles seem like a good idea, I'm by myself around here. The local RACES/ARES guys insist on using Molex connectors as their standard (IC-22A compatible), ignoring that they aren't rated for the current their modern equipment uses.

Tom & Sam-

That is what I was going to suggest. It is a common practice to send a partially reduced carrier that doesn't eat up a lot of power, but allows you to synchronize to it using a synchronous detector.

When detected, the carrier translates to zero frequency relative to the modulation, so it can be eliminated by a DC-blocking capacitor.

I think such a system is in use by some foreign broadcasters. (I'm thinking one is at 21.455 MHz?) It doesn't sound quite right using an AM detector. It can be received on an SSB receiver, but you have to carefully tune it so music sounds right.

If you insist on the 1 KHz pilot tone approach, you could end up with both the pilot tone and a small vestige of the suppressed carrier. Your filter system might lock-up on either the pilot tone or the carrier!

Seems to depend on the distributor, then. One merchant from whom I
bought PowerPoles at Pacificon a couple of years ago included them in
the bag. PowerWerx sells them separately, and I don't bother buying
them.

Are those the old-style stamped-metal round Molex pins, such as one
finds in a PC power supply cable, or are they using the flat-metal
"OEM T" connector used by a lot of the radio manufacturers these days?
I can't tell from the picture in the IC-22 manual I downloaded.

I really loathe the round-pin Molex - it really doesn't seem like a
design that will either stand up to repeated cyclings, or handle a lot

of current.

Well, "disgustingly cheap" but requiring MORE steps than a mouse
wheel
can be done by a spare gear of around 40 or more teeth. I just
tried that
with an 80-tooth gear that's been in the junkbox for decades. Used
an
optical interrupter but had to Dremel open the spacing (cut the base
of the
plastic mounting).

Gear teeth are cut with precision and even rejects are good enough
for this
kind of adaptation. About the only problem is that the openings
aren't as
abrupt as the mouse wheel...but that is easily overcome by a Schmitt
trigger inverter...and perhaps some shielding from ambient light
into the
interrupters' photosensor. Used a Fairchild interrupter costing
about $2, left
over from another project.

I mentioned the Robert Dennis circuit for its simplicity in using
ALL the
transitions possible of a sensor wheel. That's twice as many as a
more
common dual-D FF decoder circuit. Takes three packages versus one
to
get all the transitions for Up/Down outputs for direction sensing.

NOT the space shuttle, yes. I've worked on the instrumentatin for
the
space shuttle main engines (at Rocketdyne) and understand the
complexity
and reliability needs for man-rated spaceflight. :-)

If you are going to lock onto it so that that signal is exactly 1khz,
why not just cancel it with a 1khz signal 180 degrees out of phase?
This is essentially how an FIR filter would remove it digitally, but
you don't really need to generate the tone FROM the signal since you
know what it is already.

3416. A F.A.Q. for Ham Radio

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-22 21:25:01 UTC
From: Polymath <invalid@invalid.invalid>
Message-ID: <42e163e0$1_1@x-privat.org>

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing

of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

OED definition of 'ham'....

ham

• noun 1 an inexpert or unsubtle actor or piece of acting. 2 (also
radio ham) informal an amateur radio operator.

• verb (hammed, hamming) informal overact.

— ORIGIN perhaps from the first syllable of AMATEUR.

3423. Re: Anderson 'Powerpole' Connectors

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-23 00:36:50 UTC
From: RadioGuy <nospam@nospam.com>
Message-ID: <CigEe.24033$5N3.18493@bgtnsc05-news.ops.worldnet.att.net>
Source record: 17957

After trying all the permutations and combinations of connector arrangements I have concluded there is no way the 'PowerPole' connectors can be configured to prevent a short-circuit as the connectors are presently designed.

However, if the dovetails are altered (redesign of the injection mold) the connectors can be oriented 'on top of ' as opposed to the current 'side by side' orientation ---the new design will then allow the connectors halves to mate only ONE way. The connectors will no longer be 'mirrored' and as the 'PowerPole' connectors do not posess a gender a standard will be required regarding which connector half is used for the supply side and which is used for the equipment side. It is highly unlikely that Anderson will redesign the 'PowerPole' connector to meet the needs of the Ham community.

It amazes me that this connector, with the potential of short-circuit from misalignment, could be considered a standard for power connections of emergency communications equipment. In review of the literature no mention is made of the possibility of improperly mating of these connectors. This must be the first time in my experience that equipment and power source must be fused to prevent a short-circuit resulting from improper connector mating---unbelievable. I think the 'PowerPole' connector has the earmark of a classic 'Ham boondoggle'.

This would eliminate the perceived (and actual) benefit of having a
genderless arrangment, which lets you plug a battery into a radio
(acting as a supply) or into a charger or power supply (acting as a
load, for recharging), or into a distribution panel alongside radio
connections (acting as a floating backup to a mains-powered supply).

> It is highly unlikely that Anderson will redesign

Agreed.

The PowerPoles have been around for quite a while, and have seen a lot
of use in fields other than ham radio. I'm curious as to whether you
can cite evidence that the problem you forsee, actually occurs in
practice?

> In review of the literature no mention
>is made of the possibility of improperly mating of these connectors. This
>must be the first time in my experience that equipment and power source must
>be fused to prevent a short-circuit resulting from improper connector
>mating---unbelievable.

All power sources must be fused, in any case, in order to provide
protection against short circuits. In a mobile setting, it's canon
that both the hot and neutral should be fused, as close to the battery
as possible, in order to avoid dangerous ground-wire currents if the
alternator ground wire pops loose from the battery.

I'm not convinced that the PowerPole arrangement requires any
additional fusing, above and beyond what's normal and appropriate for
ham gear. Proper fusing on the hot side of the source ought to be
sufficient to result in an immediate fuse-blow under any PowerPole

misconnection arrangment I've been able to envision.

As I see it, if a PowerPole set is correctly wired, there are four ways to try to mate it.

One is correct, and works. One has the connectors rotated 180 degrees out of phase - doesn't mate, no problem.

One way has them rotated correctly, but offset in one direction - radio's "hot" goes to supply ground, radio's ground is unconnected (or occurs via the antenna or chassis mount). This one seems completely benign, as the radio is connected only to ground - radio doesn't power up, but there seems to be no potential for damage.

The fourth case is the only arguably problematic one, as it connects the supply hot to the radio ground. This seems very likely to blow the supply fuse, either instantly or the moment the radio chassis touches ground. I don't see the need for a separate fuse in the radio's own ground lead, as long as the supply fuse is of the proper value for the installation.

> I think the 'PowerPole' connector has the earmark
>of a classic 'Ham boondoggle'.

I concede the possibility, in principle, of mismatings of the sort you mention. I've not ever heard of any occurring in practice.

It shouldn't be difficult to modify a VFO-tuned CW transmitter to
transmit RTTY. You could do this with a varactor diode, in parallel
with the main tuning capacitor - drive the varactor with a two-state
variable voltage, to shift the transmit frequency the necessary number
of Hz.

If you have a VFO-tuned CW transceiver, which uses a varactor to
offset the transmit and receive frequencies by the appropriate
distance to generate a receive sidetone, then this transmit-offset
circuit could probably be modified pretty easily for dual-offset RTTY
operation.

You might need to retune your receiver bandpass filter to widen the
passband a bit... this would depend on the mode and the rig.

You might be able to do something similar to this with a
crystal-controlled QRP rig, but I suspect that pulling a crystal that
far with a varactor might be somewhat difficult.

This basic approach was, I believe, the preferred one for RTTY
transmission years ago, back before sideband rigs had good carrier and
opposite-sideband suppression. It can result in a cleaner RTTY signal
than you'd get if you use AFSK modulation into a sloppy sideband
transmitter.

Doing more-sophisticated digital modulations (e.g. PSK31) would
probably require starting with a sideband rig.

Technically speaking, your post was at best impolite. There are plenty
of people who have killfiled the OP, and your thoughtless action
resulted in their KFs being bypassed. There are also plenty of people
on dialup, who may have already downloaded the OP's rubbish, and don't
want to pay again to download yet another copy. And, by the way, I
suggest you put further posts where the sun doesn't shine.

I designed some of the first TCXOs , simple oscillators manufactured
they used no agc control and relied on the average oscillator
maintaining circuit gain to drop to limit oscillation level. Hence
clipped sine.
I.E gain during the transition and no gain during limiting.
This output then coupled to a buffer amp for isolation was the
Lowest cost option.
When logic compatibility was required a logic buffer or open collector
provided.
Also I note that (many years ago) when the first prototypes were
required I looked through a junk box for any small case and selected
most appropriate arbitary case.
These TCXO OCXO case dimensions can now be found as standard from many
TCXO / OCXO manufacturers around the world.

A further note the ssb noise will depend on the crystal Q the noise
level in the compensation circuit and the level of crystal oscillation.
Best with no compensation circuit ie XO or OCXO
The smallest crystals cannot be driven as hard as the bigger ones so
dont go for the smallest case!
The easiest way to indicate ssb noise may be to beat two identical
oscillators together with a few HZ offset.
Or lock one to the other using the voltage control line (exclusive or is
the easiest PLL circuit?)
The display the lock voltage on a scope.

Mica used to be cleaved and plated then a lower costt mica reconstituted
was employed all were silver evaporated.
Dipped refers to the encapsulation.
Low values had their tc altered by the encapsulation material.
Modern npo ceramic chips are Much? Better. Also some porcelain are the
best for Q ie loss.

Can't figure why an individual needs to qualify a group as diverse as amateur radio operators in such a manner as this. Trying to describe amateurs is like trying to determine what color of blue the sky is. However, if only more ham were curious about how their gear worked or liked to experiment or had the patience (most important) to design their own gear. Sadly, many couldn't work their way through a block diagram of their simplest gear and don't have the desire to study and learn. I guess most hams have heard by now that the code requirements will be eliminated from the US licensing requirements. My hope is that there will be an influx of technically inclined/curious people who prior to the proposed change were not interested in CW and now will consider becoming amateurs. Homebrew is not the endall for being a "good" ham and is not for some any more than participating in public service should be. It is just interesting if not exciting to see what clever circuits that some guys (many non amateur) design. I consider myself a very average homebrewer, perhaps a "bit" behind the technology of today as I still build some tube gear. But over the last year the most satisfying contacts I have made have been with amateurs that had complete scratch state of the art homebrew stations. It was interesting pitting my 70's and 80's technology against their state of the art though.

Dave-

They are the old-style stamped-metal round Molex pins. These may be a smaller size than the ones used for PC power supplies, so current rating would be less.

Polymath-

Perhaps Harold knows something that would justify his statement. I notice that you use a nickname, don't list a Ham call and hide your address. You wouldn't be one of those trolls I've heard about, would you?

For myself, I object to your fake "FAQ". It is a statement of bigotry in disguise, and very few of us can meet your criteria. You insult any of us who care to enjoy the social and other aspects of Ham Radio, in spite of your "friendliness" reference.

Get a life.

You continue to behave like a 5-year-old, especially
in respect of the lies that you tell below.

1, The harassment was _ALLEGED_ in _TWO_ malicious and
deliberately misleading perjurous statements made by Brian Reay G8OSN
on the 7th and 21st Feb.
2. No-one had any success in their complaints to my ISP. All complaints
were discussed with me. All anonymous complaints were ignored. All
complaints
from those who had a history of childish outbursts directed at me, such as
you,
were ignored.
3. I did not resist arrest. I now have the video of the arrest to prove
this.
4. When there are a large number of dangerous paranoid loonies
such as yourself on Usenet, everybody is advised to remain anonymous,
5. You have no photograph of me at a rally. The photo you do have was not
taken
when I was arrested, but when I contacted the local paper.
6. I do not have an "F6 Macro Key", whatever that may be.
7. If you wish to killfile me that is no problem. My remarks on Usenet
are not directed to the closed mind or the brain-dead mind.

In a differential capacitor, as the rotor disengages from one
set of fixed plates, it engages with the other set, instead of
engaging with fresh air.

The two sets of fixed plates are adjacent to each other and
separated by a gap. (If it were not for the gap, there would
be a solid square of metal with the axle dead centre)

The powerpole connector system is in use worldwide !

Take a trip to any home depot, sams, costco or lumber yard.

The electric battery operated lift equipment all use the large
powerpole connectors (36volt 600ah wetcells)

They only go in one way, can't put them in backwards.

We just have to watch what we are doing,
Anderson can't do it for us.

Just like at the firing range, you can load the wrong
type of ammo in your pistol and have the round get
stuck in the barrel and if fired again the firearm can
break and hurt you and others around.

What is to stop me from connecting the radio
cables to my astron termainals backwards ?

Be safe !

Dear all

I am sure this has been posted before, but I cant recall the response.
I have several 12V gel cells out of UPS's which are dead.
Apparently they can be revived by desulfating them - any ideas on the
way to do this?

Thanks
Richard

======================
Apply briefly a high current to break the sulfate by charging a high
capacity electrolytic capacitor (>10000microFarad) to say 40 -50 V (or even
higher) and discharge via battery.

The reason for having a 'dead' sealed battery can also be that the battery
has been overcharged resulting in lack of electrolyte.

Some people have been successful to 'revive' an electrolyte starved battery
by getting access to the rubber vent caps ,removing these temporarily and
injecting a minor amount of distilled or de-ionised water with a syringe.

A sealed battery is NOT necessarily a 'gel' type.

There is a lot of useful info on sealed batteries on the Web. Google is
the usual tool for that.
A good site is : http://www.buchmann.ca/

The RTTY offset is only 170 Hz, so the required detuning on 160 m would be about 100 ppm (parts per million), at 80 m 50 ppm, at 40 m 25 ppm and at 20 m 12 ppm. This should not be too hard for a VCXO, which usually can be pulled to several hundred ppm with only some spectral purity or stability problems. Shifts less than 100 ppm should not be too hard.

Hello Richard,

If they are 0 volts, recycle them, not worth the effort
to try to bring them back. They may have an open cell
overcharged or had a surge in the ups.

Most hamfests have used batteries available with
plenty of life left in them. We swap out our
batteries after three years normal use in our
small and large ups systems (data center).

Not all sealed lead acid batteries are gel cells.
GelCell was a trademark of Johnson Controls
and my still be so.
Any other sla type is absorbed electrolyte or
paste. There is the absorbed glass mat,
fiberglass keeps the electrolyte close to the plates.

> way to do this?

Sealed lead-acid (not all are "gel" types) can SOMEtimes be
revived. First and foremost: If the battery measures zero volts, don't
even try. Recycle it.

If it shows 10 or so volts, it may have developed a bad cell.
Revival can be attempted, but don't expect miracles.

The best possible method to revive any weak rechargeable battery
is with an electronic battery conditioner, such as those made by Cadex
or Christie. While very expensive if purchased 'new,' used ones often
show up on Greed-Bay, or at ham swap meets. Such a device will often use
a tightly-controlled 'pulse' charge/discharge method, which helps
destroy things like sulfiting without damaging the battery in question.

Happy hunting.

Actually they are correct. I ran an experiment using a Barker and
Williamson low pass filter with a 32 MHz cutoff.

With the set-up below the SWR went high when the amp was turned on.

RADIO===>AMP===>SWR METER====>ANTENNA

With the set-up below the SWR stayed at 1.1:1 with and without the amp
on.

RADIO===>AMP===>LOW PASS FILTER===>SWR METER===>ANTENNA

Also the output of the amp showed about 110 watts without the low pass
filter, but with the low pass filter the watt meter installed after
the low pass filter showed about 75 watts. That means about 30 watts
was being transmitted above 30 MHz even through the fundamental was at
28 MHz.

I doubled the value of the capacitors going form the collector to
ground, and the SWR dropped to 1.5:1 with the amp on and 1.1:1 with
the amp off. Then I add 470 pf capacitors from the trasnsitor base to
ground and the SWR with the amp dropped to 1.3:1 with the amp on.
With the TVI filter in-line the SWR is 1.1:1 with and without the amp
on.

A lack of working space inside the amp case made it difficult to
install a pi-network on the input and output side of the transistor
finals.

Thanks for everyone's help. The SWR increased was caused by harmonics
above the fundamental frequency, and they were outside the bandwidth
of the antenna.

Hi Group,

I am looking at moving the old CB up to 10meter CW/SSB, One thing I have never seen is the addition of a BFO circuit to copy SSB and CW.

The radio has a first IF of 10.695 MHz and the next one is 455KHz.

I believe that 455KHz is the place to add the BFO and I think that the 455KHz IF must be mixed with another frequency, say either +/- 1KHz to get the sidetone.

I don't know if this would work for SSB reception?

How about Double-side band modulation, it would have both LSB and USB but at least it would be interesting to experiment with.

If you know of a circuit or article, please post.

I look forward to your posting.

Hello to all.

I have followed the thread about variable capacitors recently and would like to suggest a piece of simple but effective software that will provide info about building your own home brew capacitors using a variety of spacings and dielectric material to get the capacitance you might need.

You may find this on the website of VE3SQB at www.ve3sqb.com

Scroll down the screen until you see the title "For the Experimentor."

The mechanics of building are up to you, but I have found it to be a great help in designing.

3483. Re: Anderson 'Powerpole' Connectors - Two SOLUTIONS...

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-25 20:21:42 UTC
From: Steve Nosko <suteuve.nosukowicuz@moutouroula.com>
Message-ID: <dc3hkm$i2f$1@engnntp2.cig.mot.com>
Source record: 17866

Roll pin problem:
I use the smallest plastic tye-wrap instead of the roll-pin. Looking at it, I reasoned the roll pin was a bad solution because of the way it stresses the wedge side-mate structure. I use the standard Power Pole configuration (for the battery charge option and commonality with everyone) and put the "head" of the tye-wrap so it is on the "top" when viewed from the "red-on-the-right" standard view. Pull the tye-wrap through all the way, so the head is up against the Andersons, then bend the rest around, to the rear between the two wires and tighten (not too tight or it will also tend to spread the two Andersons). I crease (fold and squeeze with pliers) the tye-wrap so it is "square" at the bend points. This way the two mating tye-wrap "heads" are on opposite sides (for a blind ham in the area) to mate by feel.

Offset bad-mate problem:
One solution to the "offset connection" problem is to add an empty body on the outside on each side, then fill it with epoxy. This'll prevent mating red to black. Perhaps one of you enterprising fellas will approach Anderson with a proposal to manufacture such a blank. It doesn't need to be full size, just enough to block the offset mate. It only needs the wedge side-mat and a front end in the shape of an "L". If it has a small hole in the front, it could also be used to chassis mount the pairs.

From: Ben Jackson <ben@ben.com>
Message-ID: <slrndealle.1vpi.ben@saturn.home.ben.com>
Source record: 17867

I got a bunch of identically (but cryptically) marked crystals that I wanted a ballpark idea about so I built the oscillator part of the Pixie II (up to Q1) and put a scope on it. It was around 20MHz, so I grabbed my HT and tuned around 20MHz to see if I could find it (this, by the way, is why you should not borrow the lcd display from your frequency counter for another project...). What I discovered was several signals above 20MHz (eg 21.040) that only existed when the oscillator was on. I assumed it was picking up something else and mixing it with 20MHz so I tried to find the original signals at 1040kHz but I couldn't. The "mixed" signals were very clear and strong. It was some kind of news (shortwave?) in an Asian language.

Where else should I have looked for the base signal? ~41MHz would be in the middle of a government band.

YOu can build a BFO for either one of three frequencies.
1. Near the input signal
2. Near 455 khz
3. near 10.695

It will almost have to be variatable as the CB rig will be crystal controled
and unless it has a fine tuning control (most of the AM units did not).

>higher) and discharge via battery.

That's the "trick" for possibly fixing a shorted NiCad, but it won't
fix a sulfated lead acid cell. Sulfated cells can only be recharged
extremely slowly. They will exhibit a high cell voltage while doing
this, but trying to charge them faster with higher current will only
electrolyze the water in them and damage the plates.

>The reason for having a 'dead' sealed battery can also be that the battery
>has been overcharged resulting in lack of electrolyte.

Absolutely right! There's no way to charge a lead acid battery that is
dry. You can add water to some, but some are so well sealed that you
have to destroy them to get in there.

>Some people have been successful to 'revive' an electrolyte starved battery
>by getting access to the rubber vent caps ,removing these temporarily and
>injecting a minor amount of distilled or de-ionised water with a syringe.
>
>A sealed battery is NOT necessarily a 'gel' type.

Right, but you can tell a lot by the voltage across the cell while
it's trickle charging. Gel cells, starved lead acid cells, and regular
lead acid cells all share the same chemistry and will show 2-2.4 volts
per cell, NiCads and NiMH are 1.2-1.4V, and Lithium cells run about
3V. Of course none of this works if the cell is dry.

A LOT of these die just by drying out. Injecting a bit of water is a
good idea if you can get in there.

Could your crystals just be oscillating at 21.040? A real frequency
counter can be really useful in cases like this.

I have some for sale if you, or anyone is interested.

If you have an AM CB you will be able to receive DSB by the addition of a BFO. It might work for sending CW, since it is an unmodulated carrier afterall (some 10m beacons are recycled CB RTXes). You won't be able to transmit SSB, though!

> The radio has a first IF of 10.695 MHz and the next one is 455KHz.
>
> I believe that 455KHz is the place to add the BFO and I think that the

Correct. You need to inject a 455kHz into the second conversion mixer. You don't necessarily need to phisically connect it to the circuitry, over-the-air coupling should suffice.

> I don't know if this would work for SSB reception?

Sure it does! (provided your starting point has AM reception).
See my pages http://spazioinwind.libero.it/ik1zyw/hardware/osc455.html and http://spazioinwind.libero.it/ik1zyw/hardware/osc455notes.html for some operating notes. Please disregard the circuit shown since there are better solutions.

> How about Double-side band modulation, it would have both LSB and USB
> but at least it would be interesting to experiment with.

With an external BFO you'll be actually receiving DSB, so no discrimination between U and LSB. CW stations will appear twice as you tune up the band. Anyway, since 10m at this time of the solar cycle are not too crowded (from the European point of view), you should not suffer opposite sideband interference from off-frequency stations. Making the BFO frequency agile should overcome your channelized CB limitations.

I haven't been playing with this setup for a while, but it works.

The photo Win pointed to in the original posting shows the cap across the relay coil, I believe, where it may be used to keep inductive kickback under control (caused by trying to suddenly discontinue the current through the coil, when the drive turns off, presumably). Diodes are sometimes used for that, but can slow the relay down.

>From what I've read about the caps in ignition systems, I think Win is pretty close to right. I've seen pictures of points operated in a system with too large a cap and with too small a cap, and both show more contact wear (transfer of metal, actually) than with a proper-valued cap. The result the pix showed was pretty non-obvious to me at the time, and thus stuck with me. Later work in spark spectroscopy explained some of the reason. I would expect the largest voltage at the coil output with minimum capacitance (winding+stray). V=L*di/dt, and minimizing the capacitance maximizes the di/dt in the inductor. Note that when the points open, there's no energy stored in the cap, so it's just the inductor energy that goes into making the spark.

Cheers,
Tom

If they are very strong, perhaps you can use a relatively poor antenna so it only picks up strong signals and try putting it into scan

It helps to know:
1- How did you determined the "..around 20MHz..." number.
It could actually be 1/2, 1/3, 1/4 that freq.
2- Were you able to hear the true, exact oscillator signal with the receiver.
3- the IF of the receiver used and
4- what frequencies you had the reveiver tuned to when you heard these signals.

The front end of these wide coverage handhelds are pretty broad with almost no filtering. The oscillator can easily act as an L.O.

Where F1 and F2 are the oscillator and the receiver L.O.:
The result can be F1 +/- F2 +/- the IF frequency.

Then it can be N * F1 and N * F2 that can be the culprets where N = 1, 2, 3. Chances are pretty good that the signals are not much above 20MHz.

Use a spreadsheet to do the math and it is easier to cover all these cases when you have some frequencies to enter.

Why would you want to re-invent the wheel !!!

There are millions of old 40 channel AM/SSB Cb sets available that are
easily convertable to Ten Meters with a exacto knife and a bit of solder

IS THIS A TROLL !!!

Possibly he's interested in it precisely because of the
experimentation and learning required? Because it might increase his
own understanding and skill level, as a result of figuring out how to
do it?

That is, after all, one of the justifications for amateur radio here
in the U.S.!

(see below)

The problem you describe is a nightmare and is not that uncommon but may be very hard to fix. I can only speculate on a few things. One is spurious parasitics (that term covers a lot of situations, including chip behavior that is not part of the specifications). Your oscillator circuit may be oscillating on frequecies (self modulation of the fundamental by the non-fundamental or harmonics and mixing, too?) other than the crystal fundamental. Yes, the mixing could be in your test apparatus other than the test oscillator. Sometimes if you get the receiver hundreds of feet away from the oscillator, then the spurious signals fade out faster.

Another way to approach this might be if you use a different receiver (different local oscilator freq, different IF) and see if you pick up the same sets of signals.

How about what do you get when you try different crystals? Similar spurious emissions? Try this if you can and tell us what you get.

Do you have a _good_ crystal that you know oscillates and know what its frequency is and put that into your test circuit. Does it behave as you expect? I also know and have had crystals that will oscillate in one oscillator circuit but will not oscillate in others. Also, some crystals will NOT oscillate on their fundamental but _will_ oscillate on one or more of their harmonics. Weird but true.

Thanks for sharing your results with the rest of us. That's a good experiment you described. The only "final clincher" would be if you had a receiver that covered the spectrum where you might find out what the spurious signal was that was being generated. Most power transistor circuits I've seen have all kinds of weird bypassing, ferrite beads on power-carrying lines, funny adjustable variable capacitors in funny places in the circuit. Good luck otherwise.

Hi there Paul,

I took a look, the circuit looks good, so why the better method comment?

If this 455KHz injected "over the air" signal is captured by the receiver, should the s-meter provide a constant signal level?

If the SSB signal is coming in strong (S9), and the captured BFO level is S3, will the amplitude of the BFO have to be increased?

How about AGC on the BFO so that its injection level is a function of signal level?

Thanks again for the information!

Source record: 17880

Hi all,

I have a TS-120 and I think the ears are a little weak, comparing the rig with my 757, the s-meter on the 757 always reads more.

The 120 has a cal signal knob, I put the cal signal out on 14.2 MHz and get S-3, on the 21.2, it back up to S-7. The best output is at 29.2 with a little over S-9.

I don't understand why it takes a dip in the 20 meter and in the JJY band, since JJY band is for WWV at 15 MHz just above the 20 meter band then it would use some of the same circuits.

The lower bands, 80 meters is putting out the least.

I did see where a wire had been cut and this wire was touching just behind the last waper on the RF board. It emitted smoke while listening in the 20 meter band but not in the other bands.

As far as using a signal generator, I have a wavetek 3001, I could determine a signal down to about -100dbm on 20 meters and down to about -110 dbm on 15 meters.

I did not have any reference data before the event.

If you have a TS-120 and can look at 14.2 21.2 and the other bands as the band switch is moved and tell me your reading, it may tell me if I need to search for a defective part.

As far as I could tell, the unit still draws about 20 amps into the dummy load so output power did not change.

That "smoke" part is very indicative of something wrong and should be a
good lead for troubleshooting!

> comment?

Well, at that time I wanted to experiment how ceramic filters worked, so I built a very low frequency oscillator and filtered out the wanted signal near 455k. There is also a slight overhead using just 1/6th of a TTL chip!

Subsequent studies and experiments taught me that an RC oscillator can be sufficiently stable at those frequencies. I believe a 455k RC oscillator can be built right away.

> If this 455KHz injected "over the air" signal is captured by the
> receiver, should the s-meter provide a constant signal level?

I experimented the external BFO only on those cheap multiband SW radios, and they have no s-meter.

Moreover I am personally not too interested in meter reading unless I am measuring something (ie difference between two signals). I prefer to evaluate a signal by ear.

If you need/want to rely on meter readings, remember that an additional BFO will give you AM->DSB, while you'll be listening to a SSB signal. That's half power, the meter should read 3dB less than actual strength (half point?!).

> If the SSB signal is coming in strong (S9), and the captured BFO level
> is S3, will the amplitude of the BFO have to be increased?

I do not remember having to deal with BFO amplitude. In "complex" receivers there might be some implications with AGC, especially if it follows the 455k mixer (doubt so, it is probably after the 1st conversion). Assuming the AGC on the 1st IF, then the 455k IF signal level is rather constant, so BFO amplitude should not need adjustments.

> How about AGC on the BFO so that its injection level is a function of
> signal level?

That is becoming too complex for a simple solution, IMHO. :-)

Let us know how you decided to proceed and how it worked.

Greetings from the other side of the Atlantic (and a bit of Mediterranean as well),

Erk - hi all,

you need to get a very basic book on radios, and read up the theory -
it will improve your fault finding no end. (probably mid 70's ARRL
handbook would be a good primer)

The sig gen is irrelevant at this stage - you have already proved that
by observation of the S meter during Cal (thats one of its functions
along with calibrating frequency)

Also, unconnected wires and/or smoke are a basic radio no no.

This is going to be hard --- to try and fix a radio by remote
control, but will give it a try if you want to persevere.

I'm not so sure that any book would help with a specific model problem.
After all, the OP is a licensed ham wih a callsign and *should* be
savvy enough to look for where the smoke came from.
At this point of troubleshooting it would seem that OP would be equally
served with a book on "Olifactory Recognition" inasmuch as an
electronics book. One cannot simply read a 30 year old ARRL Handbook
and fix a complicated modern radio.

Ok, I'm back with a couple more questions, since y'all are so
informative... I know it's not a true xtal set if I add an amp, but
wouldn't the best way to minimize the drop between the unloaded and
loaded Q be to add an amp? With a transistor/op amp, it seems that you
could tailor the load imposed on the tank circuit so that it's minimal,
while it seems a headphone load would be pretty significant (depending
on the headphone)...?

Also, I've seen some schematics with transistor-based and Op amp-base
amplifiers. Generally speaking, are there advantages/disadvantages to
either transistors or op-amps as the first-stage RF amplifier?

Thanks again for all the information!
Dave

In my set I simply use an audio matching xfmr. I'm using sound-powered phones which are in the 200 ohm impedance range, and around 50 ohms DC. A little xfmr like the Calrad 45-700 is a good choice. Some of the guys use a switchable matchbox using a tapped xfmr like the Bogen. You can see some of these at http://www.crystalradio.net/

As for an amp...mine plays great into my computer's sound card! I tried a little one chip amp but it only had about 20db of gain which isn't really enough to do a lot of good.

Yes, by using an amplifier, you can lower the loading caused by the detector. There is an optimum load impedance for the detector output in terms of best output power for a given input signal, and for small signals it's a pretty high impedance (resistance), because the diode's dynamic impedance is quite high for very small signals. You can find info on this at the Agilent web site (at least till Agilent sells off their semiconductor business...). Look for ap notes and data sheets covering zero-bias detector diodes. It gets a bit technical. But the optimum load is, as a rule, rather high resistance. An FET-input amplifier chosen for low input voltage noise is probably ideal. HOWEVER, the crystal radio purists would probably complain that it's not a crystal radio then. As Bill says, a matching transformer can help you out a lot. I've done some work using zero-bias Schottky detector diodes driving DC amplifiers to look for small signals, and can detect signals down in the few tens of microvolts---but the output is in the vicinity of a microvolt at picoamp currents.

The other thing that lowers the loaded Q of the coil is coupling to the antenna. Remember, the antenna looks like some impedance. A resonant antenna looks like a resistance, and an antenna coupler or tuner will make a non-resonant antenna look resistive also. And that resistance, coupled to the tank coil in your crystal radio, will lower the Q. If you couple too lightly, you won't get all the signal you can, and if you couple too heavily, you will lower the Q so much that you won't get the desired selectivity. It's a balancing act. In fact, in a multiple-resonator tuner, the bandpass shape is adjusted by changing the coupling from one resonator to the next, which changes the loaded Q of each resonator. When you have but one resonator, you just change the bandwidth (and signal level) as you change the coupling and loaded Q. Coupling that's too light mostly just changes the signal level, with minimal change in bandwidth. Coupling that's too tight mostly changes the bandwidth, with minimal change in signal level.

Hope these thoughts help some...

Cheers,
Tom

3506. MSK Demodulator

I've seen a number of inquiries about minimum shift keying, it's generation and demodulation. I haven't been able to find anything to recommend on the web, which is frustrating since I built a MSK receiver for my Master's thesis about 15 years ago.

So I've posted my Master's thesis. It goes into some detail about MSK, it's generation and demodulation. It also goes into some detail about maritime DGPS data link requirements which I assume no one cares about -- but it's there if you do.

Thanks go to Joel Kolstad, KE7CDV, for scanning 88 pages from a bound book and making them look good enough to post without embarrasement.

Hi, Tim -

There was an article in the January 2003 issue of Circuit Cellar by Tom
Napier concerning MSK.

See http://www.circuitcellar.com/magazine/150toc.htm to purchase the article.

Other than this, I've not seen anything on the Web either.

Cheers,
John

In theory, one could also use a synthetic inductance, aka 'gyrator". I took a gyrator based audio oscillator that used 741's and on LTSpice rebuilt it using 1000 Mhz GBW op-amps. Using an FFT of a transient analysis I had a nice narrow adjustable center frequency peak of about 10 Mhz, But I never did have a chance to wire it up, as I have a baby to take care of.

Most of the gel cells from UPS type supplies are baked to death! They
have been trickle charged until the gel is now dry paste. I have seen
then so badly over charged that The cases are distorted, and the terminals
are being forced right out of the case due to plate growth.

Probably not worth your time to even attempt. New gel cells are cheap.

> -Bill

Hi Bill,
no, the arrl book wont tell you how to fix a kenwood ts-120 - but it
will provide you with the basic theory of

1) how it works and
2) how to start logical fault finding.

Unless you have at least block level understanding of what is in front
of you, then you wont have ANY chance of fixing it.

Besides, by modern standards, the ts120 IS an old, simple radio, and
SHOULD be able to be serviced in the home workshop. You just need to
have enough basic radio theory to start working your way through. The
license qualification gets you on air - thats all. And most people
forget the theory unless it is subsequently applied in practice.

To me, at any rate, the 'fun' bit of AR is building and getting things
to work - I have no real interest in talking to people on air !

And RF is my field of interest - digital is a mystery, and am quite
content to ask for help and guidance if I have a problem.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

KJ4UO-

You shouldn't use the S-Meter to compare radios. S-Meters usually don't tell the truth to begin with, and then some companies make their radios read higher to make you think they are better.

Somewhere it is written that a meter should read S-9 with 50 microvolts RF input, and that for each S-Unit there should be a 6 dB change in RF signal. You can check this with a calibrated signal generator. However few radios will meet these specs and not everyone agrees with the values. In other words, it isn't as much a "standard" as such things as the AC voltage and frequency coming into your house.

To check the receiver's "ears", you need a calibrated signal generator to find the lowest signal level it can receive. That is its sensitivity, and that is what you should use to compare radios regardless of S-Meter reading.

3522. VFD as an audio/RF amplifier?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-07-29 22:32:51 UTC
From: N9WOS <n9wos@nobugatt.net>
Message-ID: <n8yGe.510234$cg1.402200@bgtnsc04-news.ops.worldnet.att.net>
Source record: 17905
Cross-posted to: rec.audio.tubes,rec.radio.amateur.homebrew,sci.electronics.design

Has anyone ever tried using a Vacuum fluorescent display as a tube type amplifier? In case anyone is interested, I have been toying around with one, trying just that. Here is my findings.

VFD was pulled out of an old VCR. Made by NEC model number FIP14KM6. I soldered all the grid leads to one wire running the length of the display. Same with the anodes. That created a tube with basically one long grid running the length of the tube, and one long anode plate under that.

All test was done with 5V on the filament.

I could easily obtain 60mA of emission current from the filament with less than 30V tied to the grid and plate. I didn't try to push it any higher because the filament started showing noticeable extra heating near the side connected to the negative of the filament supply. (ie) the filament on the left side of the tube glowed a noticeably brighter orange than the right side at the 60mA emission level.

Space charge around the grid with the grid and plate disconnected was about -2.2 to -2.4Vin reference to the most negative side of the filament.

Now to get useful output.

Hooked the plate up to a 0V to +60V supply with a current meter in line. Hooked the grid to a +15V to -15V supply with full zero crossing capability. I found that the grid in the tube is almost 100% effective. With the grid at zero volts in reference to the most negative side the filament, the plate current was only about 0.25mA. When the grid voltage dropped below -2.6V (a little bit lower than space charge) the current level dropped below readable levels. (0.01mA). The crossover from cutoff state to operating range is almost exactly 0V.

It appears that the grid pretty much acts along the lines of a space charge control grid. Efficiency in that mode of operation is about 50%. For a yield of about 1 to 1 current gain. When the control grid is positive enough to pull 2mA current, then the plate will also be subjected to about 2mA as long as it is more positive than the grid. If the plate drops below the grid voltage then plate current will start to drop and grid current will rise. As long as the plate is at a higher voltage than the grid, then plate voltage doesn't have much effect on plate current. Because of that, I was easily able to obtain a voltage gain close to 100X with a large value plate resistor.

Grid/plate curve was almost perfectly straight from 10V to 60V(cutoff) plate voltage with a 1V P-P input.

Because of it's 1 to 1 current gain, normal cap/resistor inter-stage coupling networks are useless. The driving network will basically have to be designed like a cathode driven tube circuit. Except that the output is 180 degrees out of phase with the input, instead of in phase. For audio applications, that means that all inter-stage coupling will have to be transformer based. Current gain would be performed by the transformers, and voltage gain would be performed by the VFD's

And audio amplifier was easy to build on the workbench. Hooked the plate up to 60V through an output transformer, with the transformer driving and speaker. The input was via another transformer with a positive grid bias supply hooked to it. I adjusted the positive supply to set the plate current to the middle of my desired operating range. It worked quite well.

On the frequency response side of things, it has a hefty inter-electrode capacitance. But it still provided good amplification at 2MHz. As long at a tuned plate circuit was used. Even with the large inter-electrode capacitance, self oscillation was still impossible even with a tuned plate and grid, because of it's close to 1 to 1 current gain. On a standard tuned grid, or Hartley oscillator you have to have more turns in the plate circuit, than in the grid circuit, or there won't be enough drive to drive the grid to sustain oscillation. The only working types of oscillators you can use the tube in is circuits with transformer feedback to allow current gain.

It makes it a very harmonically stable tube for RF amplifier applications. That gives me a few ideas for a full QSK QRP amplifier. Run it with zero grid voltage. It will be operating in class B. It would be good for CW or AM.

Another application, if you had two identical ones, is a push pull class B audio amp. Have the center tap of the grid input transformer fastened to ground, and the center tap of the output transformer connected to HV. Just two VFD's Two transformers, B+ , filament supply, and nothing else.

I have no idea what the maximum voltage is, that you could run on the plate. The audio amplifier I had was driven by a 60Vsupply, through a transformer output, with the lowest peak plate voltage of around 10V and the highest peak plate voltage of about 140V to 150V. It had about a quarter watt peak output, with 6mA Q current. I estimate I could push it up to about 15mA Q current with about 1W, to 1.5W peak output with 100V+ B+, and a transformer that had the right winding ratio.

Other VFD's probably have totally different specs than the one I am working with. But they should still perfectly viable for amplifier implications. If the current gain is over 1 to 1 then you may have a problem with VHF harmonic oscillation in amplifier circuits. But I don't think you will find any like that, because they would exhibit VHF oscillation characteristics even in their intended applications if they had a current gain over 1 to 1. A VFD display on an clock radio that generated a birdie on the FM broadcast band when ever the "PM" label was lit wouldn't make the FCC very happy.

Now to figure out how to make a complete tube type radio out of VFD's. Or maybe, just a single tube regenerative receiver.

Another neat thing about VFD's as amplifiers is, the display flashes in step with the music beat. :-)

Now if we could get a VFD manufacturer to produce a display with 4 or 5 totally individual sets of elements, then you could produce a totally integrated tube type AM receiver with just one VFD in it. I have seen some figures factories that give an ~$5 to $8 per unit price on custom VFD's in quantities of over 10,000.

Has anyone had any experience with some sort of above ground pool leak detector? I figures if I could connect one probe to some sort of sensitive restiance (ohm) meter and put it in the water, I could maybe read the resistance between the probe and ground and then as I got closer to the leak the restiance would go down. But the restiance is WAY high.. But seems to me something like that would work. Any ideas?

Joe AG4QC

It is technical interest that differentiates the Radio Ham from the CBer.

In a world where so much is available off-the-shelf, where is the body
of technical knowledge to be found?

I suggest that it is still within fairly elementary electrical constructs -
capacitors,
inductors, and antennae. (OK, there are some auto-antennae tuners around now
for those who are determined in their CBness)

Only if he's somewhere that has RS or equivalent, which isn't true all places. I don't find Mr. Yliskoski in the FCC or RAC databases, which leads me to believe he's not on the North American continent. The name has a Slavic feel, and anyone, anywhere in the world, can have a gmail address. It's entirely possible that there's no place near him that sells brown-n-serve antennas.

Kimmo,

An efficient 11m whip probably is going to be a bit longer than 1.5m; the rear bumper might be a better choice.

If you really want to do a roof- or trunk- (boot-) mount, there is a rather sturdy-looking magnetic mount described in the web page at <http://www.qsl.net/n2ffl/ic706kmiig.htm>. The page at <http://www.arrl.org/tis/info/Mobile-H.html> discusses mobile antenna design and construction of a bumper-mounted whip that works from 20m through 6m and will handle 100W output.

It's 99" (2.5m) long at max extension, and is retracted about 60 cm (to about 1.9m) for 10m. I think that it would need to be just about 2m long to work 11m, and that's pretty long for a roof-mounted whip. With the coil in the center, it really would be difficult to keep it in place on the roof, because of the rotational moment from the forces on the coil, and it would be a real danger to traffic if it came loose.

Boot lid would be a little safer, but not much: a magnetic mount just is not as secure as a real mechanical fastening. Please consider the bumper mount.

Good luck!

I actually have played with a few old VFDs. I didn't make any real measurements, but I pushed the plate to the full 400v of my power supply with no ill effects. The only limiting factor was power dissipation. When the tube got hot enough, the glass cracked. With enough negative grid bias it was happy to sit there all day with 400v on the plate. I was surprised it didn't arc with that much of an overvoltage.

The first graph on the 12DL8 pdf will give you a good idea what it's
operating characteristics is like. The current scale, and voltages are off,
but it will give you the general idea.

That would be easy to solve. Cover the anode side with thermal grease, and
use a clip to mount it to a big aluminum heat sink. You would have something
that would look almost like a solid state monolithic amp. :-0

Having currently employment within a Japanese manufacturer of
WCDMA mobile phones and thus being exposed to the "Innards" of
such phones; following the historical challenges of making a transceiver
that would fit into a tobacco tin, is it perhaps now the time to
issue a challenge to come up with a complete transceiver design
fabricated to the size of a postage stamp?

Some of the circuits that I am engaged in testing have components
that are smaller than the smallest blob of solder I can melt!

Perhaps it is time to extend my soldering iron with a tip fashioned
from a dressmaker's pin?

Fred - its irrelevant here - you are quite correct, but its irrelevant in this context. The S meter on the ts120 shows different readings on each band on its OWN cal. oscillator. This is what the oscillator is designed to do (among other things)

Why make it more complicated than it has to be? - keep it simple. Gets things done. Too much theory confuses the issue. Most techs earn a living by doing the SIMPLE things.

And S-meter calibration standards - yes, they do exist for sure (and they are, indeed, mildly interesting. If you have an accurate, in calibration signal generator then you can check them.) - but what about fixng the radio 1st, and THEN work out if the S-meter is properly calibrated or not.

Andrew-

Perhaps I was a little off base. It has been a long time since I had a
TS-120S, and I don't recall the calibration oscillator. I loaned the
service manual to someone several years ago, so I can't check it out!

Since I wasn't aware of the utility of the calibration oscillator, the
only sure evidence of a malfunction was a reference to smoke that seemed
unrelated to receiver sensitivity.

For what it is worth, there is a service bulletin about replacing an input
RF transformer that might have been damaged by static discharge. I don't
know if it applies equally to the TS-120 and TS-120S.

73, Fred, K4DII

SB-040

TS-120S Ant Input Transformer Replacement 7-12-79

Ts-120S transceivers subject to strong static fields or similar high
current atmospheric discharges may suddenly exhibit low RX sensitivity on
all bands. TX will be OK. You may suspect T1 on the RF unit X44-1260-01.

When replacing or ordering T1, L43-0696-35, also check the value of C20.
If it is 33pF, just replace and repeak the transformer.

First production transceivers will have a 15pF cap for C20. When changing
T1, also replace C20 with a 33pF capacitor, and repeak the circuit.

Old part number: L34-0696-05 Antenna Coil
New part number: L34-0696-35
Old Capacitor was 15pF, replace with
New part number: CC45RH1H330J 33pf

Please make these changes in your service manual.

Why the attack? A postage stamp sized transceiver is certainly quite
feasible with today's technology. It won't be QRO, but an entire transceiver
can be implemented in that size ... do a web search on "Zigbee" and I'm sure
you'll find many examples

The Canadian time and frequency standard transmitters at 3330 and 7335 kHz
are USB with partially reduced carrier. I don't see the point of sending a
tone in the middle of the speech spectrum to provide a sync reference when
unsuppressing the carrier to some degree is much more economical.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

3546. Exam Question.....

Newsgroup: rec.radio.amateur.homebrew

Because this NG has degenerated into a hotbed of infantile
personal remarks made by a number of contributors whose
only contribution to technical threads is to sneer, then this
NG has ceased to be a forum for Ham Radio and is merely an
annexe of the cesspit of the gangrenous degeneration from which
M3/CB Fools' Licensees originate.

Hi Fred,
yep - you are correct about the input transformers - they go open
circuit, and are a real bastard to replace, as you have to pull apart
the bandswitch mechanism, which usually generates its own set of nice
little problems.

I've done up 2 of them now - a nice little radio, and not too badly
made or designed, all things considered. Synthesiser is noisy, but hey,
its the technology of the time - and not as bad as some others of that
period! But can be really fiddly around the rf front end area. Things
like bandswitch wafers have run out as spare parts, most other things
are still available.

They are getting a bit old now, so have probably been through a few
owners - and if it has been "fiddled" with, can be a bugger to get all
the faults out - but usually worth the effort in the long run.

The CAL oscillator in any radio is also used as a crude signal
generator - so it gives a "quick and dirty" indication of where the
fault is - in this case, its as deaf as a post on 20m.

The loose wires around the bandswitch are a dead giveaway as well -
probably, someone has been in there in the past stuffing around. -
would look for a damaged switch contact as that might explain the loose
wires as well - someone was trying to fault find. Its unlikely to be
the input rx rf transformer as its common to all bands. The switch
wafers can USUALLY be brought back to life with some TLC - you need
more subtle tools than a big hammer, and the patience to do it tho.

73 de VK3BFA Andrew.

ps - this vintage radio is EMMINENTLY fixable at home - no custom VLSI
ics, common parts, simple design, reasonably accessible layout, NO SMD
"things"..... - if you can get a "good" one, go for it.

Thanks all for discussing the post for my TS-120.

I had the radio open to torque down the band switch knob. For some reason there was a wire that had been cut which had something to do with the 15 MHz WWV/ JJY circuit.

The radio with the wire "cut" would draw about 15 amps in the WWV/JJY switch while transmitting but would not put out any RF power. I did not keep the key down very long, in fear that what ever was drawing the current would be destroyed.

So I reconnected the wire and very little current is taken if the key is pressed now on JJY. My thoughts is that someone was trying to get the wwv/jjy switch to transmit as I can see on the schematic that is wire disables one of the radio's RF sections. Maybe a possible mod to get up to 18 MHz.

Since no power is radiated, there must be another tuned-circuit that prevents any RF.

I was listening to the 20 meter band today, while the s-meter was not giving the same signal strenght as a reference FT-757, the TS-120 could copy every weak signal the 757 could.

Cheers, de KJ4UO

==========
If you want to increase the indication of the S-meter (for example because
you wish it to be the same as on your other transceiver) ,there highly
likely is a trimpot near the meter or in the associated AGC circuit which
you can manipulate. Almost every S-meter derives its signal from the AGC.
If you have a signal generator and a good quality attenuator you can set the
S-meter indication to S9 with a receiver input of 50 microvolts @ 50 Ohms
(-73dBm).
Of course it doesn't mean that the S-meter is then correct over its entire
scale ,
1 S-point meant to be a change of 6 dB.

If car manufacturers had miniaturized their products in the same eay electronics has shrunk, then the modern motor car would fit ont he head of a pin. The only problem is who would drive it? The knobs and pushy-things would be too small to get hold of, or have you a solution for that, such as a big remote control?

It's fun to wave a magnet around a VFD. I bet you could make a fairly sensitive magnetic-field detector from one.

The best way I could think of doing that is feeding an AC signal through the filaments so that they distort in some way when in the presence of a magnetic field, then monitor the electrode current in some way to determine the amount of filament displacement that is happening. That would give you an indication of magnetic polarity, and intensity.

Second idea. Just have one grid positively biased, and monitor the current of just two anodes behind it. When the electrons move through the magnetic field, they will be shifted to one side or the other. electrode current will also shift. That would also allow you to determine polarity and intensity.

Hmm... The second idea would also work with standard vacuum tubes that have more than one anode. Or even two or more electrodes of any type that is separated from each other by a small amout, that can be used as anodes. The magnetic field would shift the electron flow from one electrode to the other. I'll have to do some experiments on that subject.

3575. Crystal Shortwave?

Newsgroup: rec.radio.amateur.homebrew

I apologise if this is not the proper group, and will greatly appreciate direction to the proper one.

I have just gotten into crystal sets after years away from the electronics feild (studied at Nuke ET "A" School and FC "A" School in the Navy in 1995-1996).

I would like to build the EconOceanic at http://antiqueradio.org/econmain.htm but the plans call for a dual vari-cap from an old superhet (using the RF section and Oscillator sections seperately to tune through the five coil pairs.) But I cannot find this vari-cap anywhere!

Here the designer shows the coverage of the various circuits in a graph. I am quite rusty (I never really worked on Comm equipment, I am a gunfire control technician by training) but if I understand this, I should be able to tune all but the lowest frequencies (.50-.75 or so) without the RF section cap (40-460pF). Again, IF I COMREHEND THIS PROPERLY, I should be able to substitute a single 365pF vari-cap for the oscillator section, ommitting the higher RF cap section, and tune all but the lowest BC frequencies.

This is fine by me since I live five miles from WSB, the local blowtorch transmitter siting at AM 750.

I just wanted to run my plans by the experts before I wind the two biggest coil pairs for this radio.

If someone wants to take the time to answer, even via email, I'll be happy to figure out how to ship a 6-pack of homemade apple cider in appreciation.

Alternatively, if someone can reccomend a different radio schematic that can tune 5810, 5850, 9955, 9975, and 13615, that too would be appreciated.

(The above freqs are for EWTN broadcasts throughout the day and night.)

Thanks

Franklin Jennings
Atlanta,GA

Hi,
I'm a crystal radio fanatic. First I'd recommend checking in with the
guys at http://www.midnightscience.com/rapntap/

I see two bigger problems than finding the cap. With WSB 5 miles away
you are going to literally be swamped with RF and may not be able to
hear much SW at all. Secondly, hearing ANY SW on a crystal set is kinda
hit and miss in the best of circumstances. The signal needs to be VERY
strong and remember that you'll have very little selectivity.

As for finding the cap...just find an old $2 plastic clock radio at a
yard sale or Goodwill store.

There's some guys on Rap-n-Tap who could probably get into more detail
about a xtal shortwave set. I built one once - with an audio amp - and
yes I heard some wispy traces of SW signals. Its anybody's guess what
frequency - or even what band - they were on.

I'd recommend building something like a 2-tube regen set - or even a one
tuber using something like a 6SN7 (dual triodes). On the same site
where you found the xtal plans I think he also has a 2-tube Doerle
receiver. Thats a good performer and if you're not into vintage tubes
thats where you can replace the two #30s with a 6SN7 or even 12AU7.
You'll find lots of these project on the web.

Good luck and see you over on R-n-T.

-Bill

I have looked at over a 100 different tube types that I have on had. Ranging from the 4 pin 01A to a bunch of different compactatrons. I haven't found one with the correct electrode structure to do a good job at detecting polarity and intensity. The only two that I found, that would possibly make a good intensity detector is the 6AV6, and the 6JH8.

You would have to have a tube with two anodes about the same distance from the cathode, with both anodes on the same side of the cathode.

(ie) the electrons leave the cathode in one direction, headed for the group of two electrodes. The amount of current arriving at each electrode will be a function of the magnetic field along the path. The magnetic field will curve the path to one electrode, or the other, depending on magnetic polarity. And the current distribution between the two electrodes would indicate intensity.

The only thing that draws even close to that is a cathode ray tube with deflection plates. Operate it with the focus out of adjustment enough that the deflection plates are pulling a measurable current. Then the current distribution between the plates will depend on how the magnetic field is shifting the electron beam.

I've started using PSpice as part homebrewing and design efforts. It is very interesting, and a great way to check out ideas before committing them to actual PC boards.

Some questions:

The version I downloaded has some limitations in the parts libraries. For example, I can't find many of the common parts used by ham homebrewers: MPf102 JFETS, NE602 mixers, etc. Where can I find the PSpice models of these parts? Has anyone developed a library of ham homebrew .MOD files for the parts we use?

I've (sort of) figured out how to put an impedance matching transformer into the circuits. I select what they call a "non-linear" transformer (bad name I think) and this allows me to set the coupling coefficient and the turns on the primary and the secondary. But what about the core material, toroid vice no-toried, bifilar windings, etc. Is there a way of plugging in the kinds of toroids we use?

Also, I'd be interested in hearing from other amateur homebrewers who are using Pspice in their solder-melting activities.

Thanks and 73

>
> Cheers, de KJ4UO

Well, this is getting a bit too much to comprehend - from your original post, the TS120 had a MDS (Minimum Discernable Signal) of -100dbm, ie 2.25uv - which is pretty poor. If your FT757 is getting the same results, then its sick too - and it SHOULD be better considering the high synthesiser noise in the TS120.

Why not read the specifications for your radios - and then post some meaningful test figures.

There is a very active Spice group (though focused on LTspice, free
from Linear Technology) in Yahoo Groups, but they have a few thousand
subscribers, many well versed on all aspects of Spice. You might
consider joining that group to get answers to your Spice questions.

Chuck Adams has a lot of spice models for typical homebrew components available on his web site, www.k7qo.net. He has a nice tutorial in the QRP Homebrewer, I think you can still get issue number 5. Also, the QRP-L archives CD has a lot of models (they may be mostly the same as Chuck though). The CD is available through QRP-ARCI.

Most manufacturers provide models of their parts, so often googling the part number will land you on a spice model.

check out the banter at the sci.electronics.cad newsgroup --
you can also google spice models

oh, for transformers -- use a current dependent voltage source -- then you
can add coupling capacitance, primary and secondary leakage inductance
etc -- unfortunately it works down to D.C.

3589. Old Miller IF Transformer Data Search... Anyone with an old catalog?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-04 00:42:04 UTC
From: Jim Flanagan <jflan@tampabay.rr.com>
Message-ID: <wvdle.34683$iG6.3423@tornado.tampabay.rr.com>
Source record: 17772

Hello...
Does anyone have an old Miller data book with the data sheet for
the #612-W4 1.6MHz IF transformer. I am planning on replicating this
part in a homebrew receiver. Of course if anyone already has one of
these xfmrs in the junk box maybe we can deal!!

Any spec info would be VERY helpful, however...

Thanks.

The problem is it could be on the bottom or sides and I need something better then my eyes to find it. It certainly is leaking as I have standing water all around the pool. The pool is 27 foot round, so a hole in the bottom could show most anyplace on any or all sides. I am hoping to measure 'something' resistance seems to make senses.. But something to lead me to the leaking location. The resistance is high between the water and the ground but measurable. I'm not sure I can see the resistance change to direct me in the right direction. I'm hoping to build or even buy something that would be maybe a bridge that would zero out or null on the restiance and then show minor changes. Something like that makes sense to me. But I can't believe someone hasn't already built something like this.

This is a crazy idea...I had one of those moisture indicators like you use with watering indoor house plants. Cost about 10 bux. Pretty sensitive but i don't know if it would help in pinpointing anything in your case.

But...if you've got standing water all around the pool it would seem to me that you need to call a pool guy. They have experience in locating these problems and you'll likely need them to come fix the problem anyway. They won't be very impressed by having to slosh thru water to view the results of your homebrew leak detector.

Yes, the 47 V 8A series regulator supply is in the big cabinet. It also has all of the protections for the MRF150 transistors. Also a fan for the 100W amplifier module. The transmitter is completely self-contained.

There is no attempt at miniaturization. I don't have the time or patience for that level of effort. Each radio is a "test bed" and not a finished product. Just this morning I made two circuit improvements in the receiver. I recently rebuilt the 3.395 MHz IF amp module and the AGC processor module to get rid of a rat's nest of "fixups" and haywire. It looks pretty good now.

I do admire the tremendous effort that goes into the compact transceivers, but I don't want to duplicate it. It is the basic radio communications functionality that I care about.

Joe-

I've never had a pool, but it seems to me that standing water could only
be the result of a gross leak. You should be able to see it with the
naked eye.

Isn't it more likely that a leak would be in the external plumbing
associated with the pool? How else could the pool have a water level
lower than the surrounding standing water, unless it is located in a
swamp?

Unless something has really changed, you shouldn't be so negative about
hearing SW on a crystal set.

About 1958, on a simple xtal set (antenna, coil, capacitor, diode, phones)
although I don't remember the exact stations (Quito and Radio Moscow?), I
do remember hearing LOUD shortwave signals. At the time, my antenna was
the top strand of a barbed-wire fence on wooden posts (length UNknown,
but probably less that a couple-hundred feet) and the ground was the guy-
wire to our house's power pole.

Build a tuned circuit for WSB and use the voltage generated as the power
supply for a transistor amplifier for your SW listening.
You will find info on the web.

This is a above ground pool with a vinyl liner.. about 27 feet in diameter, we had a special liner installed in it so we have the ground dug out so the deep end is about 6 and half feet deep. The bottom is cement as it's the only way to keep the sand from migrating along the bottom to the deep end. So a leak is a bugger to find as the liner leaks and the cement bottom send the water in all directions. I had another leak a year or so ago and I ended up draining the pool and finely found it and repaired it. In this case I can't drain the pool again, as the line probably won't take another streaching. And -ex- your probably right, I need to get a expert out here.. I live about 200 miles from Nashville and 150 from Memphis, and that's where these 'experts' probably would have to come. So if I could find this thing it would be great. I know they make some sort of electronic gismos for finding leaks, I just have no idea how they work.

Unfortunately, things /really/ have changed in the intervening years. The shortwave bands have become /much/ more crowded, and the general noise levels have increased radically - almost /every/ piece of domestic or commercial electronics radiates RF noise these days.

Bob

3607. Rules-of-thumb for RF variable cap plate spacing?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-05 13:42:50 UTC
From: Tim Shoppa <shoppa@trailing-edge.com>

Source record: 17790

Are there any generic rules-of-thumb for what variable cap (tune and load) spacing is necessary for RF amps in a certain power class?

For example, "if you're building a 80W amp with a single 6146B the plate spacing should be x inches".

Wasn't there a table in the ARRL handbook along these lines?

I'm guessing it depends on both the DC plate voltage and the power level and maybe how mismatched the antenna is.

Of course, I could just buy bigger and bigger spacing surplus variable caps until they don't arc over when I key up! Sort of how like they put the weight limit on a bridge by building the bridge, driving bigger and bigger trucks over it until it collapses, and then rebuild it with the weight of the last truck that made it over :-).

Tim.

The handbook lists peak voltages for the plate capacitor spacings.

1000 volts .015 inch spacing
2000 .05
3000 .07
4500 .125
6000 .15
9000 .25
13000 .5

Also it states that is for peak RF volts, if the DC plate voltage is across the capacitor it must be added. Plate modulated finals take about 4 times the plate voltage.

The rule of thumb I learned for HV conductor spacing is 30 KV per inch
in dry air with smooth surfaces. Rough surfaces, points, sharp edges,
etc. all reduce the arc-over voltage, as does increasing humidity.

I'd go with the handbook's table above, as it allows a safety factor
and probably will prevent embarrassing events involving smoke.

From: K7ITM <k7itm@aol.com>
Message-ID: <1123276620.770459.104560@z14g2000cwz.googlegroups.com>
Source record: 17794

Also to consider is air pressure. The breakdown voltage decreases with decreasing air pressure, and to a slight extent with increasing temperature.

"Reference Data for Radio Engineers" has a graph of breakdown for a needle gap and for smooth surfaces. For the needle gap (pretty much a worst case) at sea level (760mm Hg), it's a bit over 25kV peak at 1 inch spacing, and just over 3kV at 0.1 inches. For comparison, a couple smooth 10" diameter balls spaced with a 1" gap between them will exhibit a breakdown greater than 80kV. Plates for an air-variable high voltage cap should have smooth, rounded edges. Looks like the handbook's table assumes sharp corners, and/or gets its safety factor from an assumption of rounded edges. It's usually not much of a problem, but the higher dielectric constant (rel. to air) of the ceramic or other insulation in a capacitor can create locally higher fields that cause trouble.

Cheers,
Tom

Thanks. Ramsey have 10m and 6m RX kits, but they're FM and the beacons that I was hoping to hear transmit CW. I have a TenTec kit, but it's more complex than I had hoped and I'm told that it will work better on 80m or 40m than 10m, so I will probably build it for 40m when I eventually pluck up the courage (and source a nice vernier for the tuning).

Thanks,
- Andy, KB9YLW

Try http://www.hamtronics.com and scroll down the menu bar on the left side to Receiving & Xmtg Converters and then select VHF & UHF Receiving Converters. These will listen to any mode (AM,FM,SSB,CW,PSK31,etc.) that your I.F. rig can copy. I've built many Hamtronics kits over the years and they are simple and tune up with a voltmeter. A frequency counter might be nice to get the oscillator exactly on frequency, but it probably isn't absolutely necessary.

Oops. I see the Hamtronics 6M to 10M receive converters are only sold as assembled units, so you don't have to worry about getting the crystal on frequency! The have obviously redesigned the converters since they now use surface mount technology. Still wish they offered them in kit form as I'm not scared of surface mounting anymore...building a 10 GHz transverter right now and it hasn't been that tough. However, I need to keep up the allergy medication so I don't sneeze! ;)

> (Great quote about hammers, Mike!)

Yep - the hammer quote was great! (finally, a sensible use for
computers hi hi)

But lets look at this a bit laterally - I cant argue the figures given,
just a lowly tech. BUT consider this - you should approach it from the
viewpoint of what variable capacitors you can get hold of!

What power you are running, and thus voltage etc, is the deciding
factor - in the case of 1 (or 2 even) 6146's, its wont need all that
huge a capacitor - most surplus transmitting caps would do it no
trubble. And the traditional amateur method is, after all:-

Do the calculations, and then build it with what you can lay your hands
on !

and I forgot - the loading capacitor can be a 3 gang (typical) brodcast band one - old valve radio ones are fine. Its low impedance, so you dont need to worry too much about rf volts.

> dont need to worry too much about rf volts.
==========
When transmitter ouput is 100 W then @ 50 Ohms the V(peak) equals 100V
when output is 400 W then @ 50 Ohms the V(peak) equals 200 V
when output is 1500 W then @ 50 Ohms the V(peak) equals 386 V

So for 400 W output or perhaps a bit higher a good quality air spaced BC
variable capacitor should be OK

10M CW is fairly active when the band is open, which at this point in the
sunspot cycle is infrequent. 10m catches a little of the Es that you get on
6, but in addition, it gets real F openings which are really amazing. But
with the flux hanging under 100, that doesn't happen very often.

I would suggest you investigate DC Kits in Scottsdale, AZ, for
a kit that contains both the MC145170 and the controlling
microprocessor. Basic kit is US$35. www.dckits.com

If all you wanted was a single frequency, there is no need to
use any microprocessor. The Motorola/Freescale MC145151 can
be hard-wired at one frequency. It is available at Jameco
for US$6.00. Good up to 30 MHz. www.jameco.com

3628. SSB voice keyer from MP3 player?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-08 08:43:39 UTC
From: ollollo@hotpop.com
Message-ID: <1123490619.027009.320210@g47g2000cwa.googlegroups.com>
Source record: 17810

Hi,
I tried some googling but nothing useful came up.

I would like to build a lightweight SSB voice keyer for battery
operated portable operations (VHF contests and the like).

MP3 players are getting cheaper every day, they're *small* and
lightweight and their batteries last long enough for a typical
contest.

Has anyone seen a design of an interface between MP3 players and HAM
transceivers? Modern RTX could easily use the VOX facility, but older
gear (like my Yaesu FT-290R) would need external PTT keying.

Any idea? Would a "standard" VOX circuit do the trick?

Thanks,
Paolo IK1ZYW

Hi Andy,

Well, the reference I sent originally was for a receive only converter.
Technically, a transverter does both transmit and receive.
Personally, I would build a transverter at the start. If you hear
someone, you will invariably want to talk to them as well...

Other countries, other bands.

It appears that the UK, and possibly other countries, have allocated
some portion of 4 meters to amateur operations.

I don't want to talk to beacons, but I imagine I'll hear
some hams too and eventually once I upgrade my license it
would make sense to have invested in a transvertor rather
than just a receive converter. I no longer have a radio that
that can receive CW on any band though, so a transverter
doesn't help unless I buy a receiver too...

Source record: 17817

A part of a solution: since pretty much any commercial mp3 player will handle stereo, assuming sufficient channel separation, put your desired voice on one channel and a tone on the other channel. Then use a simple circuit to sense the tone and key a relay (or maybe even just turn on a FET) to turn on the transmitter. Use a fairly high frequency for the tone, and the response could be very quick. In simplest form, the tone detector might not need any frequency filtering at all--just detect presence vs absence of a signal. Difficulty is that you need a way to put the tone on with the voice--easy enough if you can pre-record all you need, but a bit more difficult if you want to change the messages real-time. An advantage over simple VOX is better control of the time the xmt line is activated.

I'm not sure if it would be any value, but you could also use different tones to key different things; standard DTMF would be one way to do it, but even just properly chosen single frequencies could work. And if the player can reproduce high audio frequencies OK and you only need voice bandwidth for your audio out, you could even put both the tones and the voice on one channel, and filter the tones (or let the xcvr's audio path-if filters do it).

Cheers,
Tom

In just one month, this group has grown to 73 members with a pretty lively forum - the archive of 160 on-topic messages is publicly visible. Several members are actively experimenting with a variety of homebrew sync AM detectors. The member-only links, files and photos sections have grown to have a respectable body of reference material.

Check it out - your old receiver might get a new lease on life with an add-on sync AM detector for better audio quality and sensitivity and you'll have some fun doing it! Seasoned sync AM users/designers/experimenters - your expertise and experience couldn't go into a better group.

Tom

Well no. I've posted things in both of these newsgroups about the topic,
and I'd say you're missing whole areas of the bibliography. I sure
have no interest in joining some "club".

And if you were so interested in moving the topic ahead, you'd
stay away from those "members only links and files".

By isolating yourselves, you lose out.

Undoubtedly. We've made a start on a bibliography.

> I sure
> have no interest in joining some "club".

I suppose it is, in this respect: members can be readily ejected for bad behaviour, unlike Usenet..

> And if you were so interested in moving the topic ahead, you'd
> stay away from those "members only links and files".

That's a Yahoo 'feature' over which we have no control. (Actually, on checking, the Links can be made public but many of them point to the member-only files and photos)

>
> By isolating yourselves, you lose out.

The invitation is open to all with a genuine interest in the subject. I've seen some of your informative postings and would be delighted if you could overcome your reservation about the "clubbiness".

I have a Kenwood TM 701 that has good rf decks, audio etc. The
previous owner botched the button cell battery replacement job.
Radio does not program properly. Can only change freqs with the mic
up/down buttons.

I would like to find one that has toasted rf decks (most of them) but
has good logic Or just the front encoder board.
Willing to sell for parts as a last result if I get no answers for
k-ball unit.
Please e-mail to ron@onwisconsin.com

Thank you.

3640. Gain of 2N3866 at Lower Voltages

Hi All,

Does anyone know what's the power gain of a 2N3866 at 9, 12 and 14
volts? I know that the 2N3866 has a gain of 10dB at 28 volts.

C.W.

I did think of that too, and should be pretty easy to build with a .wav editor on any PC. My only concern is about channel separation in the pocket player, and whether MP3 compression would throw away the tone or not.

Because of MP3 compression I think the tone should not be chosen either too high or too low.

> I'm not sure if it would be any value, but you could also use different

Well, walking uphill with antenna, RTX and battery (one each) is tiring enough - that's about 3kg -, having even more radios is not for me. :-)

Thanks for your suggestion,
Paolo IK1ZYW

Ah, OK, you want to listen for beacons and you don't have a receiver. I misread what you were looking for. I thought you had some sort of receiver and wanted to listen to 10M and/or 6M. Sorry about that!!

Being a Tech class, you can transmit legally on both 10M (28.1-28.5) and all bands above 6M, so you really don't have to upgrade if you don't want to.

Here are a couple websites that may give you places to start...

http://www.af4k.com/mega/megakits.htm
http://radio.tentec.com/kits/Receiver

Good luck and have fun!!

> editor on any PC. My only concern is about channel separation in the
> pocket player, and whether MP3 compression would throw away the tone or
> not.

It depends upon the compressor and the type of compression chosen. There
are three options in most compressors: Mono, Joint Stereo and Stereo.

Keep in mind that MP3 files are really MPG movie streams with no video.

Mono is obvious.

Stereo is two seperate mono channels. This is best for programs with
multi language sound tracks.

Joint stereo is the same system used in FM stereo. FM uses a SUM track
(mono) and a DIFFERNCE track. I think MP3's use one track and a difference
track. Since it is decoded by a computer, this saves processor time
over the sum and difference which requires two tracks to be calculated
after decompression instead of one.

> Because of MP3 compression I think the tone should not be chosen either
> too high or too low.

Anything in the higher audible range, say 300 Hz on up, but 2600Hz is
sort of a standard in the telephone industry and 1000Hz in the audio visual,
so your choice may be influenced by what you can find easily.

Analog phone cells identified themselves with tones in the 5kHz range.
They were used to determine which cell your phone was actually receiving.
Obvioulsy the phone filtered out the tone.

A simple set of capacitor audio filters such as the ones used in SCAF
units would do the trick and you could use a mono signal. You just make
a 3kHz low pass filter for the audio and a 4khz high pass filter
for the control signals.

>> I'm not sure if it would be any value, but you could also use different
>> tones to key different things; standard DTMF would be one way to do it,

DTMF would be simple to use, encoder and decoder hardware is very easy
to get and well documented. The tones are audible so you would need
to use two channels, or introduce a delay to prevent them from being
transmitted.

The old motorola pagers used reeds at very specific filters. Subaudible
for signal identification and audible tones to unlock the recevier.
You may be able to find lots of them in junk bins.

> Well, walking uphill with antenna, RTX and battery (one each) is tiring
> enough - that's about 3kg -, having even more radios is not for me. :-)

You could just get a bunch of audible greeting cards (or the chips from
inside them) or use a pocket pc or late model Palm.

Geoff.

>C.W.

That must be 1watt out Class C at 400mhz value.

The spec (motorola 1978) Ft is 500mhz @15V and collector current of
50ma. Later manufacture devices have Ft in the range of 800mhz.

The gain is really a function of many parameters and often the given
numbers have to be "qualified" for a given set of test conditions.
The 2n3866 is a high gain device that is useful to in excess of 400mhz
and when used at lower frequencies exhibits the usual Ft/Fop gain
curve(gain at frequency is Ft [where gain is 1] divided by opertaing
frequency and never exceeds the DC or low frequency HFE value).
So at say 40mhz the gain will be around 50 or ~17db.

The gain of that device is tied to frequency and operating current
and circuit impedences more so than voltage. As imagined they are
interrelated. However at 13.6V the class C power gain is around 10db
at 175mhz but at 28V it will be around 13db. In class A or B circuits
the gain numbers have to be derived from the Ft and HFE as well a
circuit topology used. Typically the small signal Class A gain will
be much higher.

Source record: 17828

As Allison wrote, the gain depends on the operating conditions other than just collector supply voltage. However, a reasonable rule of thumb if you don't change the operating class or circuit topology, but do adjust the output matching network as appropriate, is that the gain would change by 3dB per doubling of supply voltage (or -3dB for halving it). Think of it this way: you get the same current, and you're only changing the voltage. Power equals voltage times current. Of course, you're limited by the transistor's breakdown voltage, and too much gain can lead to instabilities. And at very low voltages, you need to consider the transistor's saturation voltage.

Cheers,
Tom

Andy-

Check out http://www.elecraft.com/ for some quite good kits. They may not have exactly what you are looking for, but the equipment has a first class reputation.

I understand you can buy a simpler kit and add to it with upgrades later. I don't know if they have a receive-only kit or not.

Tom and Allison,

Thanks for your replies. The reason I'm asking is that I built two class A small signal VHF stages using 2N3866's, powered by 14 volts, and I'm getting only 2 to 3 dB gain per stage. Then, I was told to change the transistors to 2N4427, which are 12 volt devices. Would the gain improve by changing to 2N4427's? Please explain saturation voltage. Thanks,

C.W.

Thats horrid performance. I've used 2N3866 at 144mhz and seen far
better gains than that at 12V.

What you don't specify is the (ther than VHF) is the frequency in
use. A transistor with an Ft of 500mhz at 250mhz is going to exhibit
poor gain.

A better choice would be a 2n5179, characterized for lower voltages
and has a hight Ft. I've also used 2n5109 at 440mhz/12V with good
gain, thats what 1200mhz Ft buys you.

FYI: saturation voltage is the votages measured from collector to
ground(usually same potential as emitter) at some specified current
with the device turned on hard (over driven). Applies to switching
circuits usually.

Allison

Many factors influence a stage's power gain other than the intrinsic gain of the transistor itself. Changes in circuit components and/or topology are more likely to modify the gain than changing the transistor type.

Oops, it has been pointed out to me that TECH class does not have access
to HF. I forgot about the "new" Tech license, being no-code and thus
not having HF priviledges. I keep thinking back to the days when I was
a TECH class (early 1980s) when the TECH class had to pass the 5 WPM
code test. It's just too hard to keep all the TECH class (Old TECH,
TECH Plus, New TECH) priviledges straight! Sorry about the confusion!!

Dave, you are spamming several newsgroups with this stuff.
FA: posts have no place in rec.radio.amateur antenna, boatanchors, misc,
or equipment. It belongs in swap only.

Thanks.

Try turning your filter off, and dumping a pack of red Kool Aid (don't
stir) into the pool. The red coloring will indicate the leak.

Hello Richard,

Yes, I know that the article was printed in the appendix. However, I have not been able to find a copy of W1FB's Design Notebook from a reliable reseller at an affordable price -- it appears to be out of print.

So, I am still looking for someone who can scan the article for me.

Tim AA6DQ

3665. Re: Qst Jan 1990 article

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-11 23:28:04 UTC
From: Dino Papas <kl0s@cox.net>
Message-ID: <kl0s-3AE99D.19280411082005@news.east.cox.net>
Source record: 17698

There are a couple of corrections that were made in the version printed
in the Design Notebook. Here are two that I found:

The value of R24 in Figure 1 was omitted in the original; it's listed as
a 56 ohm resistor in the notebook.

Also, a note that appeared as "Feedback" in the March 1990 QST added a
220 ohm resistor from the output of voltage regulator U2 (LM317) back to
the the "Adjust" pin and top of R1 (voltage adjust) in the power supply
circuit (Figure 3).

Tim -- if all else fails and you can't find the updated article I'll
mail you a copy via snail mail.

BTW, you can get the PC board from FAR Circuits....I've got the board
populated but the project is down in the queue to get finished...so many
projects, so little time!

3666. FS: Lots of homebrew amplifier parts

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-12 00:06:31 UTC
From: ae4en@bellsouth.net
Message-ID: <1123805191.503802.267580@g14g2000cwa.googlegroups.com>
Source record: 17699

For sale, lots of of homebrew amplifier parts. Here's a short list:

Jennings CVDD-1000-7.5S 7.5 kv 25-1000 pf vacuum variable capacitor. Looks like it is in it's original packing but cannot promise that it is new- $150.

Jennings CVDD-500-7.5S 7.5 kv 20-500pf vacuum variable capacitor, $120.

Jennings UCSL-1000 3 kv 1000 pf vacuum variable $80

New K6SVC full wave diode assembly using 28 1N5408 diodes, 28 470K 1/4 watt resistors and 28 .01 1 KV disc ceramic caps. Nicely done on a 8 1/2 x 5 1/2 circuit board $40

Mallory 800 mfd @450 volt electrolytic capacitors, quant. 2, $10 each

Mallory 1500 mfd 450 volt electrolytic capacitors. Quant 19, appear to be new $10 each.

ETO Alpha 86 chassis, band switch, tanks, both variable caps, blower, tube sockets and mount, HV choke, loading caps, 2 relays, low voltage power supply, some wiring, other small parts and low voltage electrolytic cap. $300

ETO Alpha 86 new electrolytic capacitors. Mallory 350 mfd 450 volt electrolytics. Set of 7 for $70 or $12 each.

ETO Alpha (unsure of the model)tube socket circuit board for 2 3CX800A7's. Board #ABX-X181 Rev. A, used unknown condition. $120.00.

Lots and lots more...ceramic stand offs, jacks, switches and insulators, some small to medimum sized air variables, high voltage jacks, some more ETO Alpha 86 stuff, tanks, transmitting caps, high voltage disc ceramic. I can send pics. If you think the price is too high, don't grumble...send an offer, I may just take you up on it.

3667. Can 6146B tubes be used in GG (grounded grid)?

Newsgroup: rec.radio.amateur.homebrew

I hope that when you build your amplifier you use tubes with glass
envelopes and a window in the front panel of the Amp to show the glow .
The window would probably have to be heat proof glass with a copper
screen behind it for shielding. I would just love to have an amp that
showed off the finals and maybe even the rectifiers is you decided to
use tubes in the power supply as well.

I'm after a service manual / circuit diagram for a Marconi RC782 TX.

I've got one here that's a PA and I want to get it running on 2m. I've got it doing about 45W on 2m, but there's a lot of second harmonic coming out (10W), and me playing about isn't doing much to kill it off, so I need to look at a circuit to try to work it all out.

Can anyone help?

Sam

If it's a push pull stage, you have one transistor not doing it's job.
Should have 30-40 dB of second harmonic suppression just due to symmetry.

Hi,

My first post, and I'm already make demands ;)

Have got my a Farnell LS-30 which is variable psu 0 - 30v. It is in a state of despair, and I would like to get it up and working.

Anybody got a user or service manual for this or know of a website where you can download it...preferably for free :)

Dave

3673. Lattice-wound RF choke replacement, 50 years later

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-12 13:30:47 UTC
From: Tim Shoppa <shoppa@trailing-edge.com>
Message-ID: <1123853447.833965.298810@g43g2000cwa.googlegroups.com>
Source record: 17706
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors,sci.electronics.components

I'm fixing up some older ham transmitters. 811 or 6146 finals, etc. in the 50-200 watt class.

Invariably these have sat on the shelf for so long because the RF choke for the final died a horrible death (sometimes charred beyond recognition) in their final use. I myself have fried/burnt several RF chokes and other final components in Heathkits etc. but that was many years ago when I could order exact spare parts. Sometimes a capacitor or two is burnt up too, but these I already have in the junkbox or can buy off-the-shelf.

The chokes that burned up seem to be between 1mH and 2.5mH or so, and were lattice-wound on what seems to be a ceramic form. Maybe it's a ferrite, but I don't think so.

6146/811/sweep tube handbook construction articles from the 50's show similar RF chokes in their circuits and part numbers like "National R-100" and "Ohmite Z-214".

I look in modern catalogs and I see molded (almost certainly ferrite core) RF chokes in the right inductance (low mH) and current (100mA to a few hundred mA) range but they look nothing like the old lattice-wound choke. Are these suitable substitutes for the originals? Something in the back of my head says that ferrite core losses with all that RF across the choke will make the thing burn up at transmitter RF power levels even if I'm below the DC current limit for these parts.

AES lists some pi-wound 1mH and 2.5mH RF chokes (ferrite core) that look more like the original. Better idea for these?

If I wanted to learn to rewind the original chokes (very often they double as ceramic supports for the anti-parasitic RL network and plate caps) are there any web resources that would tell me how to wind my own lattice-wound RF chokes? I've wound my share of simple solenoidal coils in repair/homebrew endeavors, but the slices in these RF chokes seem very ornately wound. I think there's a Lindsay or similar book about coil winding, is that on my "gotta own" list?

Oh well, back to replacing those smoking electrolytics in the power supply, I know how to do that!

Tim.

3674. Sony kitchen radio

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-12 14:05:15 UTC
From: jeplett <jeplett.1tnq09@news.radiobanter.com>
Message-ID: <jeplett.1tnq09@news.radiobanter.com>
Source record: 17707

I posted this in the Antenna forum but got no replies, so I thought I'd try posting it over here in Homebrew and see if anyone can help me.

I have one of those white under-cabinet Sony kitchen radio / cd players. The radio uses a digital tuner. They have notoriously poor radio reception, and the internet is full of posts by people ranting about how Sony could sell such a poor radio.

I thought I'd ask you experts if there's anything that can be done to improve the reception. I understand the power cord is used as the antenna. I've tried stringing-up an extension cord to the power cord, with no improved reception. Could I open it up and attach an external antenna? If so, how would I do this? Any ideas, or experience with this particular problem?

Regards,

Dino,
Thanks for the updates to the article. This all started because I was cleaning out a stack of stuff and came across the board that I had purchased years ago along with a box of crystals and a pcb for a crystal ladder filter. The only thing missing was the article. Thanks to Richard, I have a copy of the article.

In theory you should be able to do so -- you'd have to be able to
identify the RF section of the thing and find the capacitors (or
whatever) that are being used to couple to the power cord.

In practice it may not be the antenna that's the limiting factor -- a
crappy receiver is a crappy receiver, no matter what you do with the
antenna. You might be able to go as far as putting in an external
antenna with a preamp, but you may still not improve the receiver
performance, and at that point you may have done enough work to have
installed a _good_ receiver into a similar sized cabinet.

Tim,

The idea behind the multiple section windings on these chokes is the prevention of unwanted resonances.

The choke must present a much higher impedance than the plate impedance over a wide frequency range. A single solenoid that has enough inductance at the low frequency end is going to have a lot of self-capacitance and will wind up (no pun intended) with unwanted resonances at some other frequency(ies) in the operating range. Above any parallel resonance the reactance will go capacitive with disastrous results.

In an attempt to control this, the chokes are effectively broken up into several smaller and dissimilar chokes connected in series.

Here is an example of a solenoid wound choke that uses different winding lengths and diameters to place resonances outside the range of operation:

http://www.qsl.net/n7ws/RF_Choke.jpg

I see no theoretical reason why ferrite loaded chokes cannot be used as long as all of the design caveats are observed.

>particular problem?

In radios of this sort that I've seen, the tuner input circuit is usually coupled to the AC powerline in one of two ways. Sometimes, there's a small-value (picofarads or nanofarads) high-voltage capacitor between the tuner input and one side of the power line. In other cases, a wire from the tuner input is wrapped around one of the power-line wires several times (I suspect it's serving as a gimmick capacitor of a few pF).

If you can identify the way in which this coupling occurs, you can probably disconnect the tuner input from the line, and bring it out to a separate jack (pin or banana) of some sort. Then, try hooking a few feet of wire to this jack, and see if you can get a stronger signal.

3680. What Is Ham Radio - A Weekly F.A.Q.

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-12 19:34:33 UTC
From: Polymath <aiyr.r.bean@lycos.co.uk>
Message-ID: <1123875273.411151.190000@o13g2000cwo.googlegroups.com>

What is Ham Radio?

(Nothing whatsoever to do with Mrs.Nugatory and
her infantile obsessive habits, that's for sure!)

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

PM:

Most of that is fictional... lots of "could have", "should have", "would have" which it suggests though...

Computer related hardware/software is where all of the engineers are coming from today.

If you feel that it is fictional, then it is almost
certain that you are one of the latter-day recruits
whose style is that of CB Radio, the very type that
I warn against.

Perhaps the horse has already bolted?

No, new technology came, amateur radio was too slow to adapt, it began the
way of the dodo and has progressed along that course beginning in the late
60's leading right up to today, and continuing...

PM:

Let me give a summary of the "real world."

If you were a child today, you would grow up with the computer.

In elementary school your first "pen pal" would be in a foreign country
and you would communicate with them via the internet. You would learn to
IM, IRC, EMAIL, MSN CHAT, YAHOO, WEB CAM, etc....

By high school you would be picking up a computer script and/or language
and at least have a basic knowledge of programming. Your first hardware
project would most likely be computer related.

Somewhere along this line, you bump into a ham or a few. You look at them
using their equipment, it is apparent the internet is superior. They lack
the ability to exchange pics, apps, music, videos, documents, etc. by
transmissions taking seconds or minutes. Then, they show you a CW key and
you are dumb struck, and leave. You return to the internet and current
technology, never to stray again... you begin a web site and consider
what position you would like in the computer field, when you grow up...

I guess you never put together a crystal set or a 1-tube radio, or designed your own VFO-controlled transmitter. I did, and from those days in 7th grade, I knew what I was going to do the rest of my life. By sophomore year in high school I learned to send and receive Morse Code at 15 WPM so I could be sure to meet the 13WPM requirement for my Ham license. At 21, my Engineering education was interrupted by the draft, and I joined the Navy to become an Electronics Technician and service radar and communications equipment for 4 years. Resuming my education, I became an Electrical Engineer and worked in industry for the next 38 years, continuously learning new things as they became current technology. I was never laid off or a victim of "reduction in force" through that entire career - - because I was a "natural" and kept my skills up to meet the needs of my employer. Ham radio is an excellent start for anyone who has a curiosity and fascination about electronics, be it represented by radio communications or computers or industrial control technology.

I was inspired by Polymath's description of the good effects of ham radio on its devotees. He should be congratulated on his explanation - - a very readable and true to life presentation.

Chuck:

Your text reminds me of some of the "motivational speakers" on TV.

I don't dispute it may well be true, for a past age, just not accurate
under todays technology and the state amateur radio now exists in...

... yesterday just doesn't matter, today is only useful for being able to
plan tomorrow, tomorrow is where it is at!

==========
Suitability of any choke for this application can be readily checked (in
circuit)with a grid dipper ,which should NOT indicate resonance within any
of the used bands.

"Polymath" <aiyr.r.bean@lycos.co.uk> wrote

> What is Ham Radio?

This message is a VERY brief attempt to explain the hobby and give some pointers on where to get more information. Almost certainly I won't answer all your questions, so feel free to ask for help. Hams are famous for their eagerness to help newcomers. I should also point out that this explanation assumes you live in the USA. Almost every country has hams (amateur radio operators), but each has their own name for the various classes of license, and the test requirements vary from country to country.

(First I have to explain something you might not have realized. In doing so, I'm going to paraphrase something written by Steve Ford, WB8IMY, in his introduction to a book entitled "The ARRL Operating Manual".)

In case you didn't know, belief in magic is a necessary requirement for all Amateur Radio operators. Of course, you won't see a question concerning magic or metaphysics on the test you take to obtain your license, but in your heart you will come to believe in that powerful, intangible force.

All of us in the hobby have felt its influence at one time or another. Some night when the band is dead as a doornail you'll be tuning aimlessly, not expecting to hear a single signal because NOTHING could be coming through at that hour. But then, rising out of the noise like a ghost, there will be a faint call from another stalwart explorer thousands of miles distant. You pounce, establish contact and both of you marvel at the fact that the conversation is taking place at all. A few minutes later, however, the signal vanishes as quickly as it came. Your rational mind will shrug it off as a quirk of propagation, but that little tingle in your gut will tell you otherwise.

If you could travel back in time to, say, 1305 AD, you'd probably be burned at the nearest stake for even suggesting that two human beings could communicate with each other over great distances without a physical connection. No doubt they would accuse you of dabbling in magic -- and they'd be right!

As Amateur Radio operators, we work feats of magic every day. Many of us have become jaded about our powers and we tend to dismiss them as commonplace. We hardly think twice when we use our equipment to sommon the elemental forces of the universe. But every so often we need to

pause and remind ourselves of what we are really doing. We need to remember the essence of what drew us to our unusual avocation in the first place: the wonderful magic of wireless communications.

So how can YOU become a magician?

First, you need to prepare to obtain a Magicians License. The Federal Communications Commission calls them Amateur Radio Operator Licenses, and they come in 3 "classes".

The Technician class license, is currently the most popular class, providing the "first taste of magic" to most new licensees. There is no Morse code examination for this license, and the written examination is not considered difficult by most applicants. The frequency bands for this license are largely "local" in nature. (You can gain access to some "long distance" bands if you pass a slow (5 words per minute) Morse examination, but this option may soon be history if a recent FCC is adopted.)

The other two classes of license are General and Extra.
These two classes have access to portions of all amateur bands, with progressively more difficult exams, and a requirement requirement to pass a 5 word per minute Morse code exam.

To prepare for the exams you will need some study material and more information about classes, examination points (the exams are given by volunteer Hams in your community), and clubs in your area. A number of organizations will be more than willing to help. One such organization is the American Radio Relay League. They are on the Web at http://www.arrl.org.

Or you can write them at:

ARRL 225 Main Street Newington, CT 06111

or call them at 1-800-32NEWHAM

Ask for their "Prospective Ham Package". It will include more detailed information, a list of classes and clubs in your area, and a list of scheduled examinations in your area. Include your ZIP code in your query so they can send you info tailored for your location.

If you are near a Radio Shack store, go there and ask for a book entitled "Now You're Talking". This book is also available from the ARRL. It contains all the information you need, including study material and sample questions for the examination for the Technician license.

Good luck, and welcome to the "magical" hobby.

Regards,

Hans, K0HB

Actually it was CB band competition between a friend and I combined with my desire to understand radio that turned me in to a ham. When I was back in school my friend and I started trying to see who could put out the strongest signal. His father bought him an amplifier to get over me. I was not going to ask my parents for an amplifier, and I did not have any money to buy one since I was a full time student. I had heard the phrase "Knowledge is power", so I decided if I could not buy a bigger amp to get over my friend I would have to out smart him with brain power.
I went to the school library and started reading radio handbooks like Bill Orr's handbook. When a radio repair tech at the local ham store realized I truly wanted to learn the science of radio he gave me a copy of the 1983 ARRL handbook for free (it was 1984 at the time). I read that book until it fell apart. Then I bought another ARRL radio book, and then another radio book, and then another radio book. I'm still doing that all these years later. The radios I talk on (a Tempo 2020, Drake 4 B line twins, Yaesu FT-101ee, and a Midland 79-892 40 channel sideband CB) were all someone else's broken door stop. None of them worked when I bought them. I repaired them all, and I made most of my antennas. When I talk on those old radios part of me smiles, because I know the only reason those radios are still working is because I put them back on the air.
Anyway after deciding to ignore all the CB radio folklore I had heard on the CB back in the 1970s and early 1980s, I learned the truth about radio from reading the ARRL handbooks. I quickly became the strongest CB station on the airways, and much of that was with self taught radio know how.
A local ham noticed I was emerging from the CB pack as a potential ham, and he started talking to me about ham radio. I aced the 5 wpm Morse code test three weeks after listening to my first ARRL code tape, and I don't even like Morse code. I aced all my exams, my 13 WPM code test, and now I am an Advanced class ham. When I passed my Advanced written test a bunch old timers circled around the VE examiners desk looking for a mistake on my test, but there was none to be found. I made a perfect score, and out of all my test I only missed one question.
One of the reasons I have not taken the Extra test is because the

old timers spit on the new no code Extra. I'm proud of my Advanced class license, and I would not take kindly to an old timer spitting on me if I had the new no code Extra.
In the past I used older equipment because I could not afford anything else. Now I can afford the best, but I find myself poking around in the old tube types and tube hybrids, because I don't know if I can service the new surface mount technology stuff. If all I could do was talk on the radio that would take all the fun out of it for me. I think the best compliment I ever received on the ham bands was when an old timer listened to all the things I was building and doing and he said; "You are a true ham". That phrase from an old timer meant more to me than any signal report or any DX contact. I am a true ham, and I started on the CB band back in the 1970s just like most other hams my age. I am not ashamed of my CB heritage. The truth is I had a blast on the CB band back then.

Michael:

Thanks for your post. (A real "BLAST-FROM-THE-PAST!")

Back in the 70's, on CB, some of the best radio years of my whole life where there... I miss them... (there was a "rubber duck" under every rock--we still got "mud ducks" though :)

Amateur radio has changed too, the bands are not as interesting... the personalities stagnant and without humor, without fun, without excitement, without youngsters, without harmless pranks, without mystery. Bunch of old guys attempting to play "James Bond", "secret agent" and attempting more structure to communication than the NSA uses! :(

I hope-against-hope the good old days of radio will return, but, I would like it to do so on new technology... some of us which remember the old CB days (days when even, good, hams had cb rigs!--or, we made do with 10 meter equip. <grin>) are on ch. 38-39 LSB (27.385, 27.395) in the central valley of calif, we are a stagnant number, be nice to have the company. Lot of mobiles so they escape the harassment of hams still waging the "old war." If you mention your call, be prepared to take some kidding...

If you ever get an opportunity--come join us! Real CB still lives in isolated pockets!

Absolutely. A self-parallel-resonant inductor above its
resonant frequency will appear as a CAPACITOR.

>Here is an example of a solenoid wound choke that uses different
>winding lengths and diameters to place resonances outside the range of
>operation:
>
>http://www.qsl.net/n7ws/RF_Choke.jpg

Excellent photo quality there, Wes. Also, it amused me to see
so MANY sections on that RFC assembly! :-) I've seen quite a
few and "dipped the plate, peaked the grid" on many an HF
transmitter of olden times using such RF chokes.

>I see no theoretical reason why ferrite loaded chokes cannot be used
>as long as all of the design caveats are observed.

I can only add that the Micrometals *free* toroid calculator
incorporates approximate self-resonant frequencies in their
program's calculations. Excellent program for toroidal inductor
design...can't beat the price! :-) www.micrometals.com

Problem is, if this is a restoration kind of project similar to
old automobile restoration, toroidal forms won't do...just
weren't many in the old transmitters of the 1950s and before.
Anything of the same construction type is going to be an
expensive special-order thing now. :-(

The days of kids being computer gurus have already come and gone. Now they just play video games and chat. Very few get interested in programming. Very few do a hardware project. They take their computers to the shop for upgrades. They only people that I have observed doing their own hardware upgrades, rebuilding computers, etc are the middle aged and the "old farts" that you seem to despise so.

I spend countless hours teaching our interns how to use email, spreadsheets, etc.

Dee:

You know you have won a soft-spot in my heart now, and I always wanna "take-the-gloves-off" when replying to your posts, and I would, except you would take it as an insult and never forgive me...

Yes, there are people like that in the world. Indeed, the top of the bell-curve are those with an IQ of 100-110 (barely intelligent enough not to drool on their work.) If your company/corp is interning them, you really should look for a position elsewhere, but you knew that...

FS: Solid state Skywalker 500 linear amp with 200amp metered power supply. Puts out over 700 watts on 75M. Amp it 9+ in appearance and 100% in operational quality. Substantially less than 80 watts drives it full power. Also has bandpass filters for all HF bands. It's very quiet and very efficient. $850.

Micrometals manufactures powdered iron, not ferrite, cores. The two materials are quite different. Among the larger manufacturers of ferrites are Fair-Rite, Magnetics, Indiana General, Siemens, and Ferroxcube.

When making an RFC using a core of any magnetic material, you need to insure that the core won't saturate from the flux generated by the DC current. This is done by including flux density in the calculations, and comparing it with the flux density which the material will support before saturating. Powdered iron cores will tolerate a much greater flux density than ferrites without saturating -- but the permeability is much lower, also, which necessitates more turns and therefore higher flux density for a given inductance and DC current. The presence of an air gap in the magnetic path reduces the flux density for a given inductance, so saturation isn't nearly as much of a problem with a solenoidal inductor than with a toroid. However, once again, there's a trade -- the air gap reduces the effective core permeability.

If you don't want to calculate the flux density, you can evaluate an inductor by measuring the inductance or RF impedance while the normal amount of DC current is flowing through it. The current has to come from a source with considerably higher impedance than the inductor's, say from a high voltage source with series resistor, or a transistor connected as a current source. The measurement device is connected through capacitors. Some saturation isn't a problem as long as the impedance remains high enough for the purpose at hand -- as the saturation level increases the impedance will drop.

Low frequency ferrite -- with an air gap -- can be a good choice for an RFC because at HF the impedance is resistive or, at worst, looks like an extremely low Q inductance. This results in an impedance that stays relatively constant for a very wide bandwidth (typically decades), and

is just about completely free of resonance effects. But again, flux density has to be considered whenever it has to pass DC current.

In fact, this isn't quite a "restoration to original build" type thing, it's more of a "fix some old stuff that's been sitting on the shelf for years and put it to use" type thing. Most of these units are in pretty good shape, and I'm guessing that after the RF chokesdied they were swapped around at hamfests for a few years with each owner realizing they didn't have that choke and passing it on to the next guy... eventually ending up with me.

In fact, Pi-w
ound chokes are still listed in the Hammond catalog and
a couple of them are stocked by AES. I ordered a 2.5mH one which ought to be able to handle the 100mA or so that a single 6146 will need and I'll grid-dip it and try it out.

I would still like to find a good reference on lattice-wound and Pi-wound coil winding in a do-it-yourselfer's workshop. I think I remember seeing a book that shows how to build a little coil winding machine that'll do some of the ornate pi winding, and now I kick myself for not buying it at the time.

Even though the choke fires took out some stuff, the ceramic core seems to be intact in most cases and I think I could rewind something useful and authentic-looking on them. (OK, I'd use enameled wire and not that funky real skinny cloth kind!). Again the intention is to put these rigs back on the air after fixing whatever is necessary. Having
powered them up, most of them are fine right up to the final stage (OK, they generally need new electrolytics in the PS) where everything stops because of plate current. I probably will replace the tubes in mostcases and I'm guessing that after I get plate current flowing again and
replacing the miscellaneous capacitors blown up in the final compartment they'll
need to be reneutralized.

Tim.

Ok John, most of my ham friends are in Southern CA, and some are mobile, so it is a heck of a struggle to copy them at times on 40 m. It would be nice to receive a good signal up here in Calgary. My antenna is just a low dipole, with 1.5kW, and they all seem to hear me just fine. Guess you mean Art Bell. Have not heard him (or Wayne Green -- is he in CA?) on 75, but have heard his splatter on 40m.

Our sked is kind of tentative, and sometimes nobody shows up. I am usually around from about 7PM Pacific time.

73,

Frank

3711. Re: Can 6146B tubes be used in GG (grounded grid)?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-13 17:20:31 UTC
From: Roger Leone <raleoneTAKEOUT@sbcglobal.net>
Message-ID: <zZpLe.6649$O07.1247@newssvr23.news.prodigy.net>
Source record: 17744

There are several considerations when choosing a tube for grounded grid (GG) operation. One of the most important is whether all of the grid connections are available on the base of the tube. In the case of the 6146 (including the A, B, etc variations), some are not. The control and screen grids come out to pins on the base of the tube, so they could be connected to ground. But the beam forming structure (identified as grid #3 on most diagrams) is internally connected to the cathode. You cannot ground it without grounding the cathode (and vice versa). In GG configuration, the cathode gets the RF drive so it cannot also be gounded. Because of this internal connection, the 6146 is not a good candidate for GG operation.

This factor also explains why you may see GG amplifiers using certain sweep tubes like the 6JB6, 6KD6, and 6LF6. They have all their grid connections available at the tube base and none are internally connected to the cathode. Other sweep tubes like the 6HF5, which have internal connections to the cathode, are not suitable for GG operations.

Having said this, I should also point out that not all tubes with access to their grids at the base are good candidates for GG operation. Among other factors are the necessity for biasing. The tubes usually chosen for grounded grid operation require little or no DC bias voltage to limit plate current and set the class of operation. An example of a tube not usually seen in grounded grid configuration is the 4CX250 series. None of its grids is internally connected to the cathode, but in order to run it in grounded grid configuration, you must still supply bias and screen voltages. Which means it is no easier to make into a GG amp than a grid driven (grounded cathode) amp. One big advantage of GG amplifiers is they usually avoid the need for bias and screen supplies.

Also, the class of operation, such as AB2 which you mentioned, is not limited to grounded cathode operation. You can have a GG amp running class AB2. The class of operation is determined by the portion of the RF cycle that causes the plate current of the amplifier tube to vary. For example, in a class A amplifier, plate current is always flowing; even during the most negative voltage peak of the RF cycle. The tube is conducting for the full 360 degrees of the RF cycle and is varying in accordance with the drive signal. In class C operation (used mostly for FM, CW and plate modulated AM modes), plate current flows during only the most positive peaks of the RF drive signal and is cut off during most of the RF cycle. The output of the tube is a series of pulses which are not a representation of the drive signal, so Class C is not a "linear" mode of operation.

There is more to this, obviously. You should read though the "Transmitting" chapters of any copy of the Radio Amateurs Handbook.

Good luck,

Roger K6XQ

One advantage of "cathode driven tetrode" (where normal grid bias and screen voltage are applied) is that you get higher power gain and usually don't need to neutralize the amplifier (technically it is IMPOSSIBLE to neutralize a ground grid amplifier anyway).

Some brands of 807 and 1625 tubes had the beam deflection plates brought out via a separate wire through the glass which was connected to the cathode outside the bulb. It was possible to remove the base and then connect this lead to it's own pin (on the 1625, or on the 807 by changing the base to one with more pins), or connect it to the screen or control grid so the tube would work in GG. Thus modified the 807 / 1625 made a good gg tube. It's also possible this was true with some brands of 6L6 tubes as well.

The 814 and 813 transmitting tubes also can be used in GG operation, they have the beam deflection plates brought out to it's own pin on the base.

4CX150 and 250 series tubes work VERY well in "cathode drive tetrode" operation. Too bad the price of these tubes is now so high, even in surplus.

The article is available in both the QST view cd set for 1990-1994,
and in the arrl periodicals cd for that year. In the former it's
a bunch of .TIFF files, in the latter it's in a .pdf file. If anyone
has either of these cd sets they could email it to you, you might want
to buy one of those cd's if there is anything else in the collections
you'd like to have.

BTW I can convert the .tiff files to a .pdf file, (using open office,
MS word can probably do it also) but I only own the
1914-1929 and 1930-1939 QST views at the moment. One of these days
I'm going to have to get some later ones (I bought the early ones
to do some radio history research).

Hi Everybody

I hope this isn't the wrong place to ask. if it is, please let me know where I should post.

I have a Kenwood TS50 installed on a boat with a SGC autotuner. The tuner is grounded to a dynaplate.

I also have a 2000watt inverter/charger built into the boat for ac power creation from 12v batteries.

Something strange is going on and I jusr don't know where to start trouble shooting.

When I transmit on frequencies like 14300MHZ usb, no problem.

If I transmit on 7628 LSB 100watts the FET's in my inverter blow up! As soon as I key the mike I hear a loud pop and there goes another fet.

I've changed them twice now and since the inverter is bolted into an awkward spot and weighs 70 pounds (it's all transformer), removing the inverter and changing them ain't fun.

Tonight I went so far as to disconnect (as in unplug) the AC supply to the inverter and switch it completely off. As in no LEDS lit, everything off.

Yet as soon as I keyed the mic, POOF. The fets just blew apart.

Any thoughts as to what might be happening?

FWIW, the coax from radio to tuner runs within about 2 feet of the inverter, the radio and tuner are powered from the batteries which power the inverter. So the inverter and radio share Pos. and Neg.

I can only think of a few ways this might be happening:

1) Radiated signal from the coax leaking into the inverter.
2) Radiated signal passing into the inverter via the shared positive or negative feeds.
3) Some weird ground loop issue.

I have no ideas as to how to diagnose this and trouble shoot it without having to replace fets everytime. And that's a big job.

Any thoughts would be greatly appreciated.

Chuck:

You ask me if I ever put ham gear together from old radios, tv's and army surplus equip., Yes, gobs... my uncle had a chain of army surplus stores. Most of that equip you just took to the air...

But, born right around 1950, I got in on the tail end of tubes. In the late 60's we were already attempting to run transistors with multi-parallel-push-pull circuits to get higher outputs on low HF. The 70's provided some decent high power transistors, in the 70's seen a lot of hybrid equip (tube/transistor), in the 80's-90's mainly transistors, even multi-KW linears designed around transistors.

Now I awaiting the next generation equip., you see it in commercial and industrial use, but very rarely in amateur shacks.

Now I play with single chip wide band oscillators... buffers, amps and finals in personal experiments, all transistor. The tube, except for greater than 2KW linears/transmitters is pretty much dead... most new homebrew amps I see are using the russian tubes, cheap if you get the right source... but the filament draw on those big amps can heat a shack!

Just look at the number of hams still running the old tube equip. henry 2KW linears, drakes, heathkits, hallicrafters, gonset, johnson, etc.... although a lot of it is still in use, it isn't built anymore... some hams just haven't adapted to building with transistors... don't ask me why...

What does spark-gap transmitters, crystal radios, regenerative, TRF, etc have to do with today? Collectors items? Junk sold at hamfests?

Most high power stuff is custom made mosfet, or commercial adapted to amateur use--if you are into homebrew...

I can't offer much help, but I would think that you ought to try this with a dummy load instead of the antenna; Dummy load hooked directly to the radio.

If nothing else, it would tell you whether you have a DC voltage/grounding problem, or an RF problem.

Here's what I think is happening.

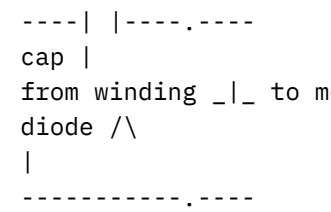
On 40 meters, the path from the tuner back along the outside of the coax to the rig is about as attractive to RF as the dynaplate, so a good fraction of the RF current being fed to the antenna goes that way. On 20 meters, the dynaplate is relatively more attractive due to a combination of the dynaplate impedance, antenna input impedance, and coax length, so more goes to the dynaplate and less along the coax.

The RF current goes along the outside of the feedline to the rig, over the outside of the rig, and into your inverter via the power leads. There are a couple of ways you can reduce the problem:

1. Put one or more good current baluns (common mode chokes) in the coax feedline. If you just put one in, I'd put it at the rig, to force the current there to be minimal.
2. Put a common mode choke in the power cable to the rig. Because the wires are pretty large, it's probably not practical to wrap multiple turns around a single ferrite core. So get some large clamp-on cores you can clamp over both conductors at the same time. It's likely to take a dozen or so, or more depending on the type of ferrite. I recommend type 43, or 70-series if you can find it in clamp-on cores.
3. Apply the same kind of choke to the inverter power leads from the battery.

What you're doing here is to create a high impedance to common mode current along the path from the tuner to the inverter.

If you'd like a quantitative measure of how bad a problem you've got and how effective any solution is (or if this is really the problem), get a clamp-on ferrite core you can clamp over the coax line or the power leads to the rig. Wind about 10 turns to make a transformer secondary winding -- the primary will be the wire passing through the clamped core. Connect the winding through a series capacitor of around 0.001 to 0.01 uF to a shunt diode (any small signal type will do), and then to a voltmeter:



Sorry, I'm not very good with ASCII art. . .

Clamp this onto the coax or over both power leads. The meter reading
will be approximately proportional to the amount of RF current. The
object is to minimize it.

Could be any of the three paths, or more than one at once... conducted
vs. radiated is an interesting question, but perhaps a bit academic.
All of your equipment is going to be in the near field of the
antenna/ground system, I think, and so you're going to be ending up
with RF pretty much everywhere.

If I had to guess, I'd guess that your inverter may have some sort of
half-bridge / push-pull switching circuitry. The RF getting into the
system is switching both sides of the push-pull drive into conduction
at the same time (a few volts of RF on the gates of the FETs could do
it) and shorting the supply through the FETs.

The fact that the RF was able to blow the FETs with the inverter
switched off suggests to me that it may be a fairly direct, local
pickup of RF onto the gates which did the damage. With the inverter
switched off, its controller wouldn't have been driving the FET(s) at
all.

As to how to prevent it from happening again... my guess is that your
best bet is going to be to add heavy-duty RF filtering to both the DC
inputs, and the AC load, and make the invert case as RF-tight as
possible.

I'm not sure whether it'd be possible to add snubbers, ferrites, etc.
on the FET gate leads themselves to keep the RF from triggering
them... the inverter design may require driving the FETs quite fast to
achieve proper control of the voltage. Figuring this out would
require a schematic and some study of the design.

It might be worth sniffing around inside the inverter with a grid dip
meter, with the power completely disconnected and everything
unplugged. You might get lucky and find a portion of the circuitry

that's actually resonant at around the frequency at which you're
having trouble. If so, spoiling the Q of this resonance might reduce
or eliminate the problem.

The intent of a "foxhole" radio was a real-world example of how to build a functional receiver under the worst of conditions and limitations. That implies using components that will "get by" in a pinch.

Basically you're referring to a plain old crystal detector set. Yes, a 1N34A diode will work much better than a razor blade and hi-z phones will work better than a telephone headset. But they didn't have hi-z phones and 1N34A diodes available in the foxholes and prison camps of WW2 and thats the legacy of the "foxhole radio".

Building one is an interesting exercise and may provide some learning experience as well as a baseline comparison for *any* other type of radio receiver. The more interesting part of such a radio is your imagination if you can imagine yourself under the same conditions totally isolated from the outside world of news and how important such a thing could be.

The downside is that the old-timey razor blades are no more. Read up on the techniques to modify newer blades...heat, corrosion, etc.

GL,
Bill

hi Tim,
yes, a reference to how to do pie-wound chokes would be good - jumble
wound would be fine, but its probably like cable lacing - you just want
to know how to do it for the sheer satisfaction of it hi hi !

the picture link that Wes posted looks pretty good aesthetically (and
evey toher way as well) - how was it done, how as the former made up -
looks like plastic, hopefully a follow-up post from The Man? - these
things also provide a useful way of getting B+ to the anodes of the
tubes......

I too have a "accidental" collection of old valve type amateur HF radios - (too many, in fact) that need to be got on air as a first step - will worry about the "authenticity" of the process later.

Occasionally it may be useful to deduce the value of the terminating impedance of an L-match network when only the values of the coil (uH) and capacitor (pF) and the frequency are known.

Program L_NETWK does exactly that.

The terminating impedance is often the input impedance of the transmission line leading to an antenna when an impedance measuring device is not available. Whereas it is possible to estimate the values of the coil and capacitor settings from a visual examination. The L and C components having been set by using the SWR meter or TLI.

The program also assists with assessing the range of terminating impedances which can be accomodated by a given L-tuner. Without such assistance a considerable strain is placed on an ordinary person's imagination.

Download in a few seconds program L_NETWK from the website below and run immediately. No unzipping inconvenience.

Since my boat, like many is made of fiberglass, obtaining a
ground/counterpoise is a tad tricky. Steel boats don't have a problem
but glass boats do.

So what is commonly done is a dynaplate is added to the boat. It's
basically a highly conductive copper plate that is through bolted to the
hull and is in contact with the sea water under the boat. There's a stud
on the dynaplate to which you attach a copper foil coming from the tuner
ground stud.

Absolutely. 25 or 30 years ago it was true. Then I could ask an exam question
which required writing an ISR in assembly, or even object.

Now, forget it! Such questions would never be allowed because the students wouldn't understand the question.

My grandkids live for the computer. the blackberry, cellphone and their gadgets, but have no idea what goes on behind the screen, despite the fact that their mother is a specialist in advanced secure systems. The kid who used to cut my grass thinks he is a programmer because he can copy a script from the internet - but say things like "object", "hex", "bus" and this teenage expert looks at me llike I have one eye in the middle of my forehead.

If I want to talk to people who build hardware, write efficient imaginative software, and can actually do hex math I go to the QCWA breakfast; where someone always has a new piece of homebrew microwave hardware or some neat little Unix trick to show off.

The last QCWA convention I attended had fascinating discussions on cell phone hacking, unix programming, software defined radio along with the old standards of antennas, propagation, etc.

Yes, I'm an old fart who can hand key 25wpm (but doesn't anymmore because e-mail is easier, not faster), use the net, write assembly programs and even use a soldering iron. I even have some idea how the telephone system works and made phone calls from my HT before the cell phone was invented. And I certainly do not rank myself anywhere near the experimenters and explorers in Ham Radio; I'm not that talented.

How can you remember that and not the £350 law book you bought less than 5 years ago?

I wonder if anyone has successfully converted a
thrown-away cell-phone into a spectrum analyser?

We would seem to have all the necessary components
in there for free - keyboard, graphical display,
post-demodulation DSP, Frequency Synthesizer,
RF good up to 1 GHz (2G5Hz if an ex-WCDMA unit)

Here would seem to be an opportunity to equip
all Radio Hams with a reasonably state-of-the-art
piece of test gear, that when coupled with an
IF generator would give us all a network analyser
into the bargain!

Many years ago it was done with junked Video Tape Recorders and, from what I saw and read, very successfully too.

Don't remember the book but I do remember several good magazine
arcticles on the subject.

Don't hold your breath, as there seems to be a raft of projects ahead
of this one: his own XRC machine, an ATU made from discarded CDs, a
DSP project using an FT-707, and of course, the mathematical basis for
the Big-K approach to DSP to be proved, peer-reviewed, and then
published.

Simple way. Wind a single layer 175uH choke on a ceramic form
with 24-26 wire. Good for 600ma and 160-10M.
I use these on all my HB from 30W to 1KW.

Dave:

No one is denying you the right to your religion of "amateur worship", we all need some high power to look up to. But, you must realize you are in a church which has a very small following (mostly other hams, and NOT all of them!)

Fact is, the computer is a TV with a tv card inserted--a stereo system with a high quality audio card, tuner card inserted--a cd music player with cd and proper software--a dvd player with a dvd-cd and proper software--a home security system with the proper card and related software and backup-power supply--and soon to be an amateur rig with proper receiver card and xmitter card (some are already there!)

Fact is, the computer IS amateurs future--like it or not... only reason the future is not here right now, old amateurs can't adapt and die first... and serve as a hindrance to the new minds bringing the future with them...

I don't know if it is the same book, but one currently available is
"Instruments of Amplification" by H.P. Friedricchs, ISBN 0-9671905-1-7.
It is available from the ARRL.

==========
Thank you for the above info. Now understanding the situation better , it would perhaps be beneficial to have a 'tunable counterpoise' between the transceiver ground connection and the dynaplate.
It is in fact an adjustable series tuned circuit comprising a air-spaced capacitor and a roller coaster or switch-tapped type of variable inductor which is tuned for minimum impedance with the aid of an integral RF current meter (as described by Roy ,W7EL) Tuning is done for each band by maximising the current in the counterpoise at low power.
For the latter it is best to use a sensitive microamp meter ,its sensitivity adjustable with a potmeter
Such a tunable counterpoise can also be used very well in a high rise apartment where there is no good RF earth .
The end of the counterpoise is then not connected ,but since the RF voltage can be considerable ,the free end should be well insulated.
Such a device can be home brewed ,but a version with a switch allowing for several inductor taps is (or at least was) available from MFJ it's their model MFJ-931 ; Artificial RF Ground.
It was (in the early 1990s ?) described in QST , by Doug DeMaw , W1FB (sadly now SK)

I have home brewed the above type of artificial ground made with a roller coaster inductor.
For the HF bands the inductor is to be adjustable between approx 0.9 to 43 microHenry ,with the variable capacitor being 200 -250 pF max.

The 'Foxhole Radio' is a type of crystal radio that can be built out of scraps that could be found almost anywhere and so it was sometimes built as a radio for soldiers to use.

There are many forms of crystal radios, most of the recent ones use a diode that can be purchased at radio shack, or any electronics parts store. This diode replaces the razer blade that was originally used as a detector diode.

Here is a website that shows how to build one.

http://www.midnightscience.com/project.html

This website has more technical information, although it shows a slightly different assembly for a crystal radio.

http://www.electronics-tutorials.com/receivers/crystal-radio-set.htm

These radios were secretly constructed and used by prisoners in Japanese prison-of-war camps during WW2 in circumstances where you can't pay a visit to Radio Shack and purchase the bits and pieces. The antenna also had to be hidden.

But, for things to work, there had to be a friendly news-broadcasting station not too far away. Which did not occur very often. Long distance short-wave stations do not lay down particularly strong signals.

However, there has been a report of prisoners in the Far East receiving news of the end of the war in Europe thus giving encouragement and hope to people who had survived for several years under the most extreme and terrible conditions.

No turns depends on dia of form but the size of the form don't matter.
I use forms from fried chokes, 3/8 inch to 1 inch.
With 26 wire and 3/8 dia, expect 3 inches of winding or so then use
analyzer to get about 170uH and check for zeros around 23MHz and a
second around 33MHz. Tweak the 170uH to get the zero at 23MHz in
situ but with the PINET unhooked...

The former, as I read the book.

Those who passed the Technician license prior to 3/21/1987, and thus passed the Element 1A (5 WPM) code test, have Novice-equivalent HF privileges as part of their Technician license.

Newer Technicians, who pass the Element 1 95 WPM) code test and are given a CSCE as proof of passing, but who have not passed Element 3 (General written exam), have Novice-equivalent HF privileges indefinitely. They should retain the CSCE as proof of this since the FCC doesn't keep track of which Techs have code credit. The CSCE is valid as credit towards the General license for only one year.

No - but we do remember the one written here in the UK and published by Ladybird books written by Rev. George 'read the quote' Dobbs G3RJV.

Maybe you should purchase or search for a copy from ebay or amazon - the wooden baseboard is roughly at your level of engineering (or should that be fettling) from what we read in other newsgroups!

You also forget the gauntlet he laid down in the newsgroups to design a transceiver that was roughly based upon re-inventing the wheel.

When people took his suggestion somewhat seriously, he backed away, and, as it the case with all Bean-powered projects, let the subject die.

Don't remember the book but I do remember instructions for taking a 1N23
or two
(many available as surplus) and opening one and adding another point
contact.
The extra point contact could be obtained from the second 1N23. At that time
the 1N23 was filled with wax so opening one up was doable.

Good luck
Bill K7NOM.

Bargain - of course - that's after the Radio Amateur has equipped his shack with a very expensive SMD rework station....

Would it not be wiser to suggest the building of an interface so the shack PC could be used to do such a task as spectrum analysis?

Beanie/Polymath - Once a dumbass, always a dumbass.

Andy-

It doesn't work that way now. However you can probably pass the General Class test with only a little more effort than for the Technician test. Many years ago they were the same test except for code speed. Check out the practice tests at http://www.qrz.com.

You may be interested to know that the FCC has issued a proposal to eliminate code from all Ham tests. It will take a while before all the comments have been submitted and resolved. If you want the HF license now without waiting, you'll need to pass the code test.

I don't remember THAT book.

I do remember the book though "How to kill beans in 3 easy steps" by "Moth Flutterus".

Very good book, well worth the read, goes into much detail.

Apparently the HQ is in Chippenham, so if any of you are out that way, stop by. I believe the road is Hardens Road or Close or something like that.

I must say though, that a good old roasted coffee bean is just the thing.

Tara a bit all

3759. Tuned MFJ-1024 Active Antenna

Hello Group

I have been wondering if it might be an advantage to remotely tune this active antenna using a varactor? The remote unit uses a 40673 dual gate mosfet followed by a 2N5109 npn vhf/uhf transistor which feeds a 30 turn bifilar wound 4:1 balun. Then rg58 to the control unit. The whip is 58"/1473mm in length. Any thoughts on this? Thank you.

Richard

(Apologies to the top posting hater community, but I decided to follow John's lead).

Got the wrong guy John.

I've been using most of that stuff for quite a while, and I could point you to a dozen or so hams well over the age of 70 who not only use it; they understand how it works and some even tinker with the hardware and software.

I'm not quite that old yet, but it ain't always that easy to keep up with some of them when they discuss their latest project.

About a quarter of a century ago, I was teaching a system using a synthesized HF sideband transceiver, on a single PCB about 2 or 3 inches square, running from about 7 to 10MHz and digitally controlled either locally or remotely (up to 100 transceivers controlled from a DEC minicomputer) - would love to have slipped one in my shirt pocket, taken it home and added a linear! Funnily enough most of the guys I was working with have decided to become hams within the last 10 or 15 years.

The HF receiver card in one of my PCs gets far more use than my stand-alone transceivers with the DSP etc. the card is much more versatile - more modes, bandwidths etc. etc.. Software defined is the way to go.

But, and it is a fair sized but, I find I can have much more detailed and interesting discussions of this technology with older rather than younger folks. I find (just my experience and maybe the folks I choose to hang out with) that the younger generation tend to be users who know no more about how it works than my granny knew about how her telephone worked. But boy can they use it!

My generation understood it down to the electron level.
My kids understood it down to the IC level.
My grand kids (teenagers - with a few exceptions) know how to use it but don't understand, or really care, how it works.

Can't blame them, it's progress. The systems have become so complex that one pretty much has to specialize and folks with a general knowledge of hardware and software, theory and practice of entire systems are becoming a vanishing breed. That is true of much more than communications technology - the guy at the corner gas station probably can't fix your anti-skid braking system any more than the local pharmacy can sell you the part to fix your TV any more.

Dave

Dave:

Interesting, when I have exchanged station pics, I have never seen the new equip, other than my own...

When I exchange equip descriptions, everyone is mentioning drake, henry, heathkit, etc... frankly, last months maybe a year--I gave up paying close attention... in fact, my xmitter pci card is a proto-type which an engineer made a gift of to me when I worked on some software to support it (they will actually market a USB model.) Last time I chatted with him, it was still sitting on his companies "back shelf" waiting for the market to develop... they strongly support dropping CW and expect an influx of new hams which they feel will accept the equipment and make profitable the sales. In the meantime they market to police, fire, hospitals, gov't...

Ken:

I think you meant to say that cathode driven tubes have LOWER power gain. Grid driven amps can have as much as 10 dB or more gain than cathode driven (GG) amps, all other factors being equal. My Johnson Thunderbolt running a pair of grid driven 4-400's can be driven to full output with about 20 watts of RF drive (representating close to 20 dB of power gain). The same tubes in GG configuration would need close to 80 watts to drive them to full output.

A grid driven 4CX250 can produce over 200 watts of output with 2 watts of drive (per the RCA manual). Because the tube isn't commonly used in GG configuration, that manual doesn't provide power gain figures for cathode driven service. My guess is you would need more like 8 to 10 watts of cathode drive to get the same 200+ watts out.

The widespread use of transceivers in the 100 watt class has made GG amps popular since there is no need to attenuate the transceiver's output. With my grid driven Thunderbolt, I use a 6 dB attenuator at the amp's input to keep from overdriving it.

With the right choice of tube, a GG amp can have a much simpler power supply. And since there is no need for neutralization, homebrewing a GG amp is quite appealing.

Fascinating, I don't know who you talk to but I can only think of a couple of people I know using Drake stuff, and then only as collectors items or though nostalgia. Can't remember the
last time I heard someone mention Henry, except in an inductor value, and one of the few pictures of Heathkit equipment I have seen in a long time was in a magazine on antique equipment a (younger) friend showed me a couple of weeks ago.

I have a real hard time believing that the long overdue dropping of CW will result in much of an influx to HF. If they were interested in HF they would already be here.

I've had a two hour HF swap shop running in the background and I don't think I heard anything that old being offered for sale or looked for except for a couple of antique RCA, Hammarlund and National receivers, but they were in the antiques listing. Plenty of DSP rigs
and digital stuff, a few people looking for specialized digital ICs. It is quite common to hear current generation equipment being sold by very elderly hams due to deteriorating health and/or moving into nursing homes or apartments where they must give up the hobby.

I'm having coffee with an 81 year old tomorrow and he has a DSP HF rig; and a software defined receiver running on his backup PC, which he also uses to watch TV and movies. He usually has at least one PC in pieces as he reconfigures it and has been inside his ICOM and
Kenwood HF rigs with a soldering iron more than once, although as his age creeps up he is reducing those activities somewhat. He will probably want to discuss optimizing the data base for his SDR receiver.

Not every ham over 40 is using a hand key to a crystal controlled 6L6.

You should take this up with the guys at Eimac. (Well the used to be
Eimac anyway).

Section 5.4 of "Care and Feeding of Power Grid Tubes" is titled,
"Neutralizing Ground-Grid Amplifiers."

Dave:

Interesting, I expect the posts on rec.radio.amateur.homebrew,
rec.radio.amateur.equipment, rec.radio.amateur.swap to change to
reflect that any day now!

Do people have their 60th birthday, and suddenly become stupid or
something? I had a PSK31 QSO with a 96 y.o. Hams last year. He was
checking out his new laptop. Had a modern rig also. That's just one
case. There are plenty other oldsters I've QSO'ed with who are trourghly
modern.

Sure looks like this bunch of young folks just didn't leave and return
to the Internet.

Any receiver capable of receiving SSB or DSP will be able to receive CW i.e. some kind of BFO is required. I don't know any way to make a CW _receiver_ in any simpler way than a DSB receiver.

Making a direct conversion receiver would be quite hard for the 10/6 m bands, since there would be a lot of problems with stability. A more practical approach would be to use a crystal controlled convert to convert the signal down to say 3.5 MHz and then use a tunable direct conversion receiver.

Most simple Rx kits for 6 m are FM only (as well as some 10 m versions), which are usually not usable for CW reception. Of course if there is only a single very strong CW in the band (e.g. monitoring if a local beacon is functioning), you might take an FM kit, locate the signal strength output at the FM-detector IC and use it to key an audio oscillator :-). Replacing the ceramic filter in the last (455 kHz) IF with a narrow filter will also help, provided that the receiver is stable enough, so that the signal will remain within the narrow filter bandpass. However, such systems are useless in any crowded bands or for receiving any weak signals.

His philosophy seems to boil down to "Don't do as I do, do as I say" -
the motto of the hypocrite.

It's been fun, gotta go catch an airplane - one of those new ones with no propellor.

Often there is no need for neutralization, but depending on frequency and
wiring layout, yes there is a need for neutralization. Usually its worse
at higher frequencies. And, it can get very very complicated, too.

I have an Ameritron 811-H (four 811s in grounded grid) and it comes from
the factory with one kind of neutralization!!!! It would not be there if
it were not needed.

I had a thunderbolt, too. And it also had neutralization built in.

I also had a Heathkit DX-40 back in my novice days and it would go into self-oscilation (big time) on ten meters if I removed the crystal or shut off the VFO. I made my own neutralization wire and fixed that. Its funny that Rangers had no built in neutralization, either. Same tube, similar (but not identical) circuit in final (6146). You don't know if you need neutralization until you do the tests (read the manuals on this).

Art, W4PON

homebrewing a GG amp
> is quite appealing.

I've built several (including a single 4-400) and I'm happy when I don't need neutralization.

3780. Linear wideband power amp

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-15 22:51:12 UTC
From: Peter Weiss <playfield-bbs@gmx.net>
Message-ID: <1124146272.794600.167840@g43g2000cwa.googlegroups.com>
Source record: 17613

Hello!

I want to build a linear wideband power amplifier with the following specs:

30 MHz to 1 GHz
input 20 mW
output 10 to 20 W

The output should not be very sensible if connected to an unmatched load. The amp is intended for EMI testing in a shielded room.

I have a few of the 2C39 tubes here... I intend to use them in a grounded grid configuration, possibly 2 or 3 stages to get the required amplification (or a pre-stage with PC86, PC88 or similar).

Any hints? Do I have to develop this from scratch, or are there any working circuits around? Everything I found was just for a small frequency area, no wideband application.

Well, that's a step in a good direction, I suppose. Their Web-site
search engine from Hell was really getting on my nerves.

Now, if they'd just quadruple the size, selection breadth, and quality
of their electronic-components rack...

Unfortunately, all their money comes from cell phone sales. I won't be
visiting them until they lose their shirt doing that and have to go back to
selling components.

3785. Homebrew AM transistor radio

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-16 04:04:08 UTC
From: wrongaddress@att.net
Message-ID: <1124165048.522692.10360@g43g2000cwa.googlegroups.com>
Source record: 17619

I'm attempting to build a small AM broadcast superhet transistor radio from scratch and having a problem with the three IF stages oscillating at the IF frequency (455KHz). The IF coils are salvaged from other radios and the ground connections are to a common bus wire that connects all the IF coil shields. It works reasonably well around 5 volts, but breaks into oscillation (at the IF frequency) if the supply voltage is increased 1/2 volt and the signal drops off significantly if the supply voltage is reduced 1/2 volt. So, it only works within a very small supply voltage range of around 5 to 5.5 volts. The IF stages are decoupled from the supply with a small resistor in series and bypass cap to ground which helps, but doesn't solve the problem. I'm wondering what can be done to stop oscillations and increase gain?

How did they manage to avoid the oscillation problems in the old tube radios that were hand wired without any PC board?

Who cares? Their stuff has been and probably always will be a POS. I
have never seen worse electronic components sold to the general public
than the junk in that store. Avoid them like the plague.

Last night I was watching on cable a movie made in 1997 about Star Trek
fans. One of the fans builds things. It showed him going into a Radio
Shack store and asking for parts and electronics help (should I use
a 270 oHm resistor instead of the 3k?).

The back of the store was a maze of parts racks, and they guy knew the
answers.

As Joani Mitchell once said "you don't realize what you've lost until it's
gone".

Try reversing the leads to one of the IF transformer windings to stop
the oscillation.

Sadly, I think them doing that - is wishful thinking. Actually, were it not for the Cell Phones and some other miscellaneous items, it seems to me that they would be out of business in the not too distant future. Electromics "toys" - can be had at Wal-Mart or any other place, same with TVs, Stereos, Computers and phone accessories. The "few" scanners they sell isn't enough to hold them. I really do think they're on their last legs. IF they go on longer, then all the better. But I think it is going to take a major miracle to pick them up. > IF generator would give us all a network analyser
> into the bargain!

If you have web access, I have built a scalar network analyser from one of the commonly available TV transmitters http://www.g6lvb.com/Articles/NetAn/index.htm.

These TV transmitters use the SP5055 2.6GHz I2C frequency synthesisers and are easily programmed from a PIC. You could build yourself a spectrum analyser using the synthesiser as the sweep oscillator as I did.

If you successfully reverse engineer a cellphone enough to be able to use any of the parts you describe I am sure that there would be a great deal of interest if you published the information for any particular model.

How about a radio the size of a PCMCIA card that you can slip into your
notebook computer? No external box required, except possibly an
amplifier if you needed it.

If this is the same project that I remember, it's based mostly around the TV tuner module from an old VCR.

The TV tuners work real nicely as they have a well-defined interface to the VCO control voltage, mixer in, and mixer out. The VCO is also the "right range" (VHF-Lo, VHF-Hi, UHF covers a lot of frequency!) at least for 50MHz up to the top of the UHF TV band. I don't know what they did for frequencies below 50MHz.

The TV tuner module is also nicely interface to (a handful of easily soldered-to pins.)

Cellphones don't really have a well-defined module like the TV tuner in them. They aren't broadband in the same way. Their synthesizers are not broadband either.

Tim.

Back in the '70 you had to demoinstrate knoweledge of electronics before
you could be hired; not an expert, but at least understand what the
customer was looking for. I worked for them until '79. Their new
slogan is "you got questions, we got insults."

Sweep oscillator on the X axis of an old junk oscilloscope and the IF stage
of an old multiband radio always did the job for me, mind you that was until
I went to university of course when we found a new use for the spectrum
analyser - listening to Radio 1 in the lab mainly.

10 years? No way. In recent years I've had a few instances to go into a RS looking for stuff for the kids like videogame machines and just odd random non-radio related stuff. They aren't competitive with that stuff either.

Seems to me that they are 'surviving' off of their convenience aspect since most of their urban stores are located in malls and many smaller towns that don't have the big box stores and malls at least have an RS franchise...but they never have a very good stock of anything. When you go into a RS and they can't fit you with a new cellphone battery whats left?

My bet is that there are a lot of red ink stores in their chain and the poor franchisees are basically working only to have a job and to try and salvage their investment. I suspect if it weren't for their franchising schemes the name Radio Shack would be long gone already.

Well RS is doing well financially, better than the competition. As for what they sell, well, you have to follow the money especially with the rents so high. Cellphones, satellite service and other modern fun things is where the money is now. Parts make up very little of the business, even though they make a high profit on them. The do-it-yourself market is pretty lean now a days, with college areas making up the biggest market. It is to easy to buy a digital rig and get it up and running than a homebrew one. Even though the homebrew one is funner to get going.
The internet also plays a big roll in the dimise of the parts draw.
There is also a few hams left at RS.

Problem with that scenario is most and I'd dare say a majority of the RS clerks didn't have a clue about electronics - to be able to give "that" type of answer. They were lucky to know what a resistor was, let alone how to substitute one value for another. They were good when they sold parts, the other stuff was for the "other" people - not into Electronics. I'm talking the toys and gadgets. For anyone wanting to go in for parts only - it has seriously lost its touch.

I wasn't meaning to compare selling cellphone contracts with selling parts that nobody buys anymore. What I meant to suggest is that they are not even the best choice in the satellite tv/cellphone package market. Sure, they get bulk deals from the main providers but so do a lot of other people who don't have to pay mall-front rent prices and can undercut them at their own game.

Follow the money is very appropo and will likely figure into their ultimate demise. I'll reitirate that its the franchise owners who are taking the beating, not the corporate entity.

If you are getting oscillations then you have a feedback loop somewhere that
you don't want. What are you using for IF amplifiers? Transistors, Fet's,
mmic's, or something else? How are you biasing the stages? Are all three
stages oscillating or only one of them? If you are using transistors or
mmic's you might be better off not even using IF cans.

> It's starting to work, Yahoo has surpassed Google.

I don't doubt that at all. "Some" did know what they were doing and/or
selling. But, by and large - most didn't. I was in a store once too where a
customer asked about a Public Service Scanner. The sales lady didn't know
what was what with the three models they listed. I overheard them asking her
about them, as they wanted to buy one. She plain said "I don't know". I
asked if I may help, she said yes. I explained to them what they needed to
know and they did buy "a" scanner. I told the young lady - I know it may not
be required, but you should at least "try" to learn a little of what you're
selling. That store wasn't a RS, but just goes to show, many sales people do
not know their products. THAT can hurt them in the end. People don't want to
or like to buy things they can't use. Especially now with the price of gas
to return something.
The Employee selling the item isn't going to look very good - whether he did
it on purpose or just plain didn't know. In the end, I think the Staples,
Wal-Marts, Office Maxs, (maybe Circuit Citys and so on are going to be in

the front. Radio Shack selling basically the same thing the others do - with the exception of a few things, will peter out. I give them 10 years tops. I hope I'm wrong, but I doubt it. I think their era has come and gone.

3808. 73' mag article "TV/VCR TUNER APPLICATIONS by W6WTU

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-17 04:49:13 UTC
From: pdrunen@aol.com
Message-ID: <1124254153.950197.205050@z14g2000cwz.googlegroups.com>
Source record: 17642

Hi group,

W6WTU put out 3 articles in 73' from April 97 to June 97.

I have the second and third, can not locate the April 97 mag in my collection.

Anyone with a scan could capture that article would be do me a good ham favor. I tryed a email address for Hugh, W6WTU but since no reply it could be an old email. Maybe he will see this post.

Basically seeing a bit of VCR dump as most all are moving over to DVD. I can get VCR from 5 to 15 dollar range and can locate co-workers willing to part with an old VCR for the asking.

There I can remove the tuner and make some interesting projects. Currently I have not made anything yet, just beginning. I have a tuner I removed out of an VCR and I am now looking for information about it.

It looks like a panasonic but has a 205052S on it, no telling. There is an exposed card with PINS in ORDER starting from the left

BT
GND
IF
AGC
NC
AUDIO
NC
AFC
+B
M
V
GND

THE OTHER pins are under the metal can and I did not see a name of the PCB either.

Maybe someone can share information about the signals and possible id the manufacturer by the line up?

Another question, I have a UHF tuner taken from a set made in the '80 and it has a knob to rotate to select one of 84 channels.

Out of the tuner is two wires and a RCA jack which goes back up to the VHF tuner.

Can any one tell me was IF frequeny is coming out of the tuner and what mine be the volt on the other two wires? The set was an RCA portable unit.

I don't know what you mean by "small resistor" in series with the V+ line. Each amplifier stage should have a series resistor of 100 ohms and a bypass capacitor of .01uF. Actually, you can bypass every other stage if you are using common emitter or common source stages, but I would do it with every amplifier stage.
As far as physical distance for each stage, you should allow 1/2 inch for every 40dB of gain. You shouldn't have this type of problem. A ground plane is always a good idea, but at the very least you should have quite a bit of ground flood on the circuit board. Although it is possible if you have quite a bit of copper foil tape around the board, you can build this circuit on perfboard but you have to be very careful, as you have already discovered. I don't know if they have perfboard that has copper on only one side, but this is one solution.
You had a question about the old hand-wired tubed equipment. With a metal chassis, you would keep the wiring down close to the chassis itself, which would in effect provide that ground plane. A ground is very important to provide a place for the return currents for all of the signals, whether physical wires or copper traces are used.

Ratshack get their income from people living in today's consumers' society
,not from the few dinosaurs who enjoy tinkering with electronics . That's
the reality . If they are reconsidering publishing a catalogue and include
electronic components ,then their marketing people and nobody else consider
this a potentially profitable move .

They wouldn't do it just to please electronics enthousiasts (which include
some home brewing radio amateurs)

Bill - BILL - I was "trying" to be nice about it - be conservative - give them time to buy themselves out of this mess. If they go 5 they'll be damned lucky. As to their "Franchising" - knowing what I do, I'd be very hard pressed to want to be a part of their system. I recall a day when they wouldn't allow (at least how I recall it) a store within 10 miles of another. Now, they have stores and francised outlets squeezed in between. Maybe in the quest to try to add more stores for more sales, - they choked themselves. Seems to be a going thing today. A big store chain comes in - claims the best of the world and within a very few short years - declare bankruptcy and shut down. Whatever their problems are - Cell phone sales - TV sets, Phones, Gadgets and so on - just aren't going to cut it. They really did lose the basis of their origins. Sad but true - a sign of the times. It wouldn't surprise me if tomorrow on CNN - they came out with the announcement that RS is calling it quits. Like the death of a famous movie

star or whatever you hold somewhat near and dear - it may startle the mind,
but life goes on.

What's wrong with, say, G-10 glass epoxy rod for winding RF chokes
around?

Is it flammability/gasses made in a choke fire that would make G-10 be
not preferred?

Tim.

No, it's the simple demographics. The parts buyers are older people with more disposable income and a technology bent. They won't sell you a cell phone, but they might get you to buy one of their big ticket items while you are there.

Let's face it, if you go to a Radio Shack once a week to pick up parts, like many of us used to do in days gone by, while you are there you are more likely to buy something else than make a trip to one of the big stores especialy to buy a $20 item. I'll bet you that they make profit on that $20 item than some of the big stores make on a $100 item.

Geoff.

Its a pain in the ass for those who walk with a cane to try to bend
down and look in the bottom drawers without falling, or knocking over
the piles of toys they use to try to hide the cabinets. One store has
them right outside the door to the office, and its dangerous trying to
stand there with the droids running in and out of the office.

I've tried several values, 220,330,510, ect. with 0.05uF bypass.
Doesn't make much difference.

> As far as physical distance for each stage, you should allow 1/2 inch for
> every 40dB of gain. You shouldn't have this type of problem. A ground plane
> is always a good idea,

The IF cans are spaced 1 inch apart and I disconnected the 2nd IF stage
so I only have an oscillator, mixer and single IF amp stage. Same
problem, it always oscillates when the voltage is raised to obtain
reasonable gain.

> Although it is possible if you have quite a bit of copper foil tape around the
> board, you can build this circuit on perfboard but you have to be very careful,
> as you have already discovered.

I took a look inside a AM/FM clock radio I have and checked the
ground connections. There are 3 RF transformers, oscillator, mixer and
single IF stage, and all of the metal shields of the transformers are
isolated. There are no physical connections between the shields of the
3 transformers.

Obviously, I am missing something. Grounding all the transformer
housings on a massive ground plane does not seem to be the answer.

You didn't say how far away from the dynaplate the tuner was? I would
bet that you have a fairly long run with your ground lead to it as
seen in most boats where the antenna system has problems.
You need to have a very short distance between the tuner and the
ground plate, not more than a few feet. Lots of people install the
tuner close to the antenna and run a long ground lead. That is the
wrong way to go as it then allows the coax and power leads that go to
the tuner to become part of the antenna system as well as the radio
itself and its power leads, which you don't want.

Also if you operate in fresh water rather than salt water you may need
more surface area for a ground.

Sail boat or power boat?

Bill,

Transistor amplifiers with inputs and outputs tuned to the same frequency turn out to be oscillators, especially if the the tuned frequency is very low compared to the transistor's Ft. If you're using a modern transistor with an Ft of say, 800 Mhz, and you're tuning it to say, 500KHz, then you could have available gain of over 60 dB in one stage. This is a sure-bet oscillator waiting to happen.

You can lower the gain by 'loading' the input and output tuned circuits with parallel resistors (try 1K for starters and work up from there if it stops the oscillation. Just remember that this technique, in addition to lowering the gain, will also load the tuned circuit and degrade selectivity.

You can also try a small resistor (less than a couple hundred ohms) in series with the collector lead of the transistor, or in series with the base lead. This technique will lower the stage gain and actually increase the impedance seen by the tuned circuits, improving selectivity.

Keep in mind that raising the selectivity too much can cause tuned circuit losses, just as parallel loading it will lower selectivity and increase losses.

I will assume good wiring, lead dress and stage bypassing have been
attended to as even small amounts of feedback regardless the cause
will insitgate oscillation.

Transistors have internal capacitance from collector to base and in
high impedence RF amplifiers that serves to couple input to output
and make a fine oscillator. The gain attainable before oscillation
was usually listed as MUG (max usable gain) and is usually specified
with a test circuit. Often that circuit was neutralized (more later)
to allow best gain without oscillation. For a .455khz IF a stage gain
of more than around 35DB from one transistor is begging for
instability.

There are several solutions for that. One is reduce the gain, not always a good solution but sometimes required. Another is to neutalize the amplifier. Neutralization is to feed back some of the signal out of phase back to the base lead to balance out the signal comming back via the collector base capacitance. Like anything enough is good too much is bad.

As it turns out most ransistor radios of the 50s up till the do it all on a chip era had to cope with unintentional feedback. Most applied both of the mentioned solutions, reduce the per stage gains and apply neutralization.

As to how to apply neutalization... Varies depending on circuit. Assuming your using common IF cans and generic transistor circuit it's usually easy. The output IF can has three terminals on the tuned side, one is meant for DC power, another is collector and the remaining is the out of phase feedback to the base via a capacitor in the range of 1 to 10pf. Which pin is which, depends of the can and who made it. Another way if the IF can is not tapped is to feed back some fo the secondary winding to the base. The tricky part here is if the secondary is backward it will make oscillation worse and you will have to reverse the seconday IF transformer leads. What you are shooting for is a stable amplifier.

One of the side effects is that if the applied neutralization is too small the stage will have some regeneration but not oscillate and that is also unstable though a very high gain state to be in. Strive for stability. The stage should not oscillate at any reasonable voltage or tuning adjustment.

All of the proceeding is predicated on the transistor stage oscillating at the IF frequency. It is possible due to various factors that the transistor is oscillation at VHF and a number of other frequencies as well. This is trickier, as you need to suppress that and then deal with the IF oscillation if still present. VHF oscillation can be killed with a 100ohm resistor in series with the collector lead. The resistor and the collector lead should be short. There is no measurable gain lost at IF frequencies to that resistor as it's size is very small compared to the load.

Having built more than few radios with high gain IF stages I've had to deal with this problem more than once. Hope it helps.

A ground plane should make the system more stable. The radios that I have
been designing over the years have gains in the I.F. systems that range from
90 to 120dB, depending on the topology. You are definitely getting signal
feedback through your power supply rails. 100 to 120 ohms is about as high
as you want to go as far as decoupling resistor values. .05uF is too high of
a value for a decoupling cap.............01uF is what you should use for
local decoupling.
You should also have at least one bulk decoupling cap that has a value in
the range of 10 to 47uF. The larger decoupling cap cancels out the
inductance of your power supply wiring while the smaller local decoupling
caps cancel out the inductance of the bulk cap.

Hi Tim,
got no idea really - over the years I have sort of got used to things bursting into flames occassionally(sp) hi hi , so dont worry about it but just give it a go and see what happens. I also dont leave things running un-attended, so am not the complete lunatic I would seem.

To me, the main criteria is whats on hand - there are not REALLY huge voltages and currents there, so a bit of latitude in the materials selection process seems to me, at any rate, quite reasonable.

No doubt one of the space shuttle designers on this group will promptly debunk my theories.....

And yes, I sometimes DO represent the lunatic fringe of radio - guess I never really grew up. But I have fun.....

If you're near a big city and its library, it's likely that the reference section would have a copy on micro-fiche. Only thing to remember is that by then it was called "73 Amateur Radio Today".

Sounds like you got this problem nailed Gary.... I would suspect that
the RF Ground between the tuner and the radio is somewhere close to 1/4
Wave and is the Power wires to the inverter are also near 1/4 Wave for
the 40 Meter band, or maybe 1/8 Wave. A couple of good RF Type .1 uf
Caps across Inverter Power Leads, at both ends, should tame the problem,
after the RF Ground is shortened up to make it a good Low Impedance,
Wideband RF Ground.

This coming Sunday....

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday August 21st 2005
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

> output.
>
Actually I meant to say that the "cathode drive tetrode" has HIGHER gain
than a TRUE grounded grid amp. The only difference in gain between a
grid driven amp and a cathode driven tetrode amp would be due to the
driving power lost in the input circuit. But don't forget that in a
cathode driven circuit, some of the input power actually feeds through
and appears as part of the output, so it really isn't 'lost'.

Your statement about needing 80 watts to get full output in gg would
NOT be true if you ran the 4-400's in "cathode driven tetrode" service.
The BIG difference is applying normal bias and screen voltage rather
than grounding both grids and running in zero bias class B. I suspect
you'd need less than 25-30 watts for full output in "cathode driven
tetrode". BTW you'd need quite a bit LESS than 20 watts drive in
grid driven service, if you ran the tubes in class AB1 where only
voltage (no grid current) is required. (But it might take THREE tubes
to get the same output as TWO in class B or AB2).

> A grid driven 4CX250 can produce over 200 watts of output with 2 watts of
> drive (per the RCA manual). Because the tube isn't commonly used in GG

>
Sounds about right. Depends on how good your input matching network is.
Those figures must be for class AB2 though. In class AB1 your IMD goes

way down and the driving power might be only 1-2 watts in cathode drive.
> The widespread use of transceivers in the 100 watt class has made GG amps

>
A newer way is to run tetrodes in grid driven service with a 50 to 200
ohm high power non inductive swamping resistor from grid to ground. NO
matching network needed, same drive requirement as grounded grid, no
neutralization. Waste of power though. Many commerical amps using
Sevtlana tetrodes using this circuit.

As other have mentioned, those salvage if cans were meant to be used
with a neutralized amplifier. You could also re-wire the if stages
to be grounded base, which usually don't need neutralization.

Also look for transistors with lower FT. Most transistors meant for
audio frequency use will give enough gain at 455khz.

3835. Re: Homebrew AM transistor radio

Newsgroup: rec.radio.amateur.homebrew

Source record: 17668

Well, I don't have an exact dB gain figure, but I hooked up the mixer stage by itself and I get about 300 to 400 mV p-p with a generator connected to the antenna coil using 3 turns of wire around the coil and a 50 ohm resistor in series. The generator is set to 400mV p-p and I get about the same amount out which is fairly stable from 9 volt supply to 6 volts.

The first stage seems to be working right, no oscillations, and stable output as the supply changes, and reasonable gain.

The transistor is a 2N4123 with a Ft of 250 MHz and hfe of 50-200. It is biased using a 1k emitter resistor at 1 volt, or about 1 mA.

I assume this stage works ok and will investigate number 2.

The thing to watch out for, and I hope this isn't too redundant, is that the perfectly working stage can start misbehaving or regenerating once the following stage is connected and activated. At least you've proven that its not self-oscillating but don't assume that it wont start regenerating afterwards due to errant coupling issues. Sounds like you're making good accurate measurements so that would reveal such a situation.

Hallo!

I am seeking some info about using transformers from microwave ovens in HF PA power supplies. As one side of the secondary winding is connected to the transformer core, I am a bit confused on how to do the voltage doubling.

Any info on the subject is appreciated.

Bill, this is really a great collection of projects that is really what radio was in the early days. It is an inspiration for all of us to do more than just recap a radio to make it play. I have been collecting part to do what you are doing some day when I retire. Maybe I shouldn't wait for that since we never know what fate will bring us tomorrow.

3865. Re: Homebrew AM transistor radio

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-20 05:49:15 UTC
From: wrongaddress@att.net
Message-ID: <1124516955.436855.299510@g49g2000cwa.googlegroups.com>
Source record: 17697

I sucessfully hooked up two stages with no oscillation problems. I added a 560 ohm load resistor across the output winding of the first stage. The LO oscillator is a separate circuit (JFET) and there are no physical connections from the the oscillator to the mixer stage. It seems to mix and produce the IF from just the radiation from the LO capacitor to the station tuning capacitor.

The IF modulated output is about 2 volts p-p on a strong station, 600 mV on a average station, and only 50mV on weak stations.

It's almost usable, but not quite. I need to raise the weak stations another 12 dB or so. Also, the LO oscillator is leaking into the output at the high end of the band. I get 100mV of noise from the LO toward the high end.

Is it a good idea to try and raise the gain of the 2 existing stages, or try to add a third stage to raise the gain?

I've noticed some transistor radios use only one IF amplifier stage while others use 2.

What are the advantages of the third stage if enough gain can be obtained from just 2?

-Bill

3866. The Weekly F.A.Q.....

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-20 07:32:00 UTC
From: Polymath <aiyr.r.bean@lycos.co.uk>
Message-ID: <1124523120.544365.180540@g43g2000cwa.googlegroups.com>
Source record: 17548
Cross-posted to: rec.radio.amateur.policy,rec.radio.amateur.homebrew,uk.radio.amateur

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

Perhaps it is that those who respond in a negative style,
or those who respond with Childish Broadcasts (CB), are
from the very group of CBers that are
warned against in the FAQ?

I just hope that we have not left it too late to
prevent Ham Radio from becoming a gangrenous
degeneration of such non-technical CBers.

Bill,

Good to hear that you tamed the oscillation, but the 560 ohm load resistor seems a bit severe...have you tried something in the few kohms range?

50 mv out of the mixer on a 'weak' station sounds pretty good. What is the combined gain of the two IF stages? Are they possibly overloading ?

Also, how are you coupling the antenna into the mixer?

Joe

3874. Op amp supply-rail question

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-20 11:14:53 UTC
From: Ian Liston-Smith <ian@morse-code.NO.SPAM.TODAY.fsnet.co.uk>
Message-ID: <312eg1he7tdtr9tvanovs7ek3n8q7f8efi@4ax.com>
Source record: 17556

I'd like to build a tone control circuit using the LF353 dual op amp. The circuit has bass, mid range and treble adjustments.

The problem:
The circuit (see http://www.ece.ucsb.edu/courses/ECE002/2C_Su05Makaremi/lf353.pdf circuit on page 7) uses dual voltage rails of +15 and -15 volts, though for line input levels, this will probably work down to +8 and -8 volts. But I want to run it from a single +12 volt supply.

Usually, two 100k resistors across the supply, their junction connected at the non-inverting input, alows an op amp to run from a single supply, the output floating at about half supply volts. This is fine for my use, but will it work with a dual op amp? I've searched my documentation, but found no reference to doing this for dual op amps. If it will work, will say two 100k resistors (one to +12v the other to ground, junction to pin 3) work? Does it need another 100k or so between their junction to pin 3 to isolate the input audio from the two 100k resistor potential devider?

The first op ampin the LF353 application notes is only a buffer in the tone control circuit, so I guess I could avoid the problem and use a single CA3130 or similar op amp and use the 100k devider trick, and still use the tone control components. (I doubt the LF353 has any special properties for this particular use.)

If anyone has another three-control op amp circuit wthat runs from a single 12v supply, I'd be interested.

Thanks...

Ian

<snippety>

> though for line input levels, this will probably work down to +8 and
> -8 volts. But I want to run it from a single +12 volt supply.

<snippety-two>

The solution: You can easily get aftermarket DC/DC converter modules which will take your +12 in, and provide bipolar 15V out.

Some examples:

Power-One, p/n DFC10U24D15, in stock at DigiKey for about $71. Vin range of 9-36, Vout +/-15 at 300mA per, isolated outputs. .PDF spec sheet is at:

http://www.power-one.com/resources/products/datasheet/dfc10d.pdf

A less expensive solution with slightly lower output voltages can be found at Jameco on this link.

http://www.jameco.com/webapp/wcs/stores/servlet/ProductDisplay?langId=-1&storeId=10001&catalogId=10001&productId=161728&pa=161728PS

If the link doesn't work, try searching for Mean Well part #DKE15A-12. This one will give you +/-12V at 625mA each, isolated output, for $35 and change.

I'm sure there are plenty of other manufacturers with products that can address your application. Happy hunting.

It will work just fine with a couple of caveats. One, there needs to be a goodly sized filter capacitor at the junction of the 100K resistors. If you can stand a couple of seconds "warm up", a 100 uF will serve admirably. Two, if the noninverting inputs (+ inputs) have any function other than bias (i.e. if there is feedback to them or they are an active input) then yes, you will need some sort of isolation resistor network. How you gin that network up and keep voltage drop from happening is up to you.

This web site brought back quite a few memories... I played around with one of the 'EE' kits in the early 60's when I was in Thailand---Pop picked it up for me when he was in Hong Kong.

http://ee.old.no/

Judging by the links presented on the page, these kits played a major role in shaping the lives of many engineers-to-be in Europe and elsewhere. I don't remember seeing these kits marketed extensively in the US although every now and then I come across a Ham's bio that contains a fond reference to them.

You could load the primary instead, values in the range of 10k to 80k
would be tried.

> The LO oscillator is a separate circuit (JFET) and there are no
>physical connections from the the oscillator to the mixer stage. It
>seems to mix and produce the IF from just the radiation from the LO

Not uncommon, one circuit copuples to another due to adjacent
components. However, the Mixer may not be seeing the optimum
LO level for best gain or overload characteristics.

>The IF modulated output is about 2 volts p-p on a strong station, 600
>mV on a average station, and only 50mV on weak stations.
>
>It's almost usable, but not quite. I need to raise the weak stations
>another 12 dB or so. Also, the LO oscillator is leaking into the output
>at the high end of the band. I get 100mV of noise from the LO toward
>the high end.

Any number of factors here. More gain means more stanility problems.

>Also, the LO oscillator is leaking into the output
>at the high end of the band. I get 100mV of noise from the LO toward
>the high end.

The LO could be noisy due to design error. The front end (loopstick
in AM BCB radios) may be tuned better at that end of the band and you
hearing (seeing) more noise. Or you are seeing better coupling of the
LO (increses with frequency) and better mixer gain. The MW range
(300kc to 3mhz) has a very high backgound noise both teresterial and
man made.
.
>Is it a good idea to try and raise the gain of the 2 existing stages,
>or try to add a third stage to raise the gain?

NO, they are only conditonally stable as is. That load on the one
transformer is both robbing gain and also giving a little stability.

>I've noticed some transistor radios use only one IF amplifier stage
>while others use 2.

Depends on perfomance. Those with one are pretty tepid in the
sensitivity department.

>What are the advantages of the third stage if enough gain can be
>obtained from just 2?

Many AM radios apply AGC to one or more stages to "level"
the strong and weak stations for even audio output and to prevent
later states from overloading. More stages allow for more applied AGC
and overall better perfomance.

Use two 10k and at least 100uf or more of filtering . Works in
designs I've built. Also insure the supply rails are well filtered
and the input and output capacitors are suitably sized.

>The first op ampin the LF353 application notes is only a buffer in

Use the buffer, the circuit will behave better with input sources of
unknown impedence.

The 353 is a nice low noise opamp.

>If anyone has another three-control op amp circuit wthat runs from a
>single 12v supply, I'd be interested.

There are but the one you have with an artificial ground point will
behave well.

Hi
I just picked up a (stoner) Dymek DA9 active antenna. The tuning cap has somehow been bypassed and it does nothing to affect the station. I was told that this was bypassed intentionally so as to be a broadband antenna. I'd like to resore ti to original and use the tuning cap as a preselector.

Does anyone have a print / schematic on this unit ?

Thanks!

I looked though my stuff and all I could find of my EE20 was a heat sink,
the ferrite rod and the Valvo OA76 diode (I think that diode came from the
kit).

Blew up components is right... I recall electrolytic capacitors coming apart
when they were hooked up wrong---I had to get new 100 mf capacitors.

I remember building the:
Vochtigheidsindicator (moisture indicator)
Automatische nachtlamp
Morse-code apparaat met oortelefoon
Morse-code apparaat met luidspreker

Did you see this link to the EE20?
http://www.rrd.demon.nl/Philips%20experimenteerdozen/foto_ee20.htm
I tried to download the pdf template file but I didn't get anything.

You're right, they were nicely put together kits. I'll keep my eyes open on
eBay for them---maybe even try the Dutch eBay.

Hi Sven,
QEX Jan/Feb 1998 has an article using four microwave oven transformers
to build a HV power supply. Glancing thru I see that a magnetic shunt is
removed from the transformers as these will cause poor regulation.
I'll read it today a see if I can add more info. I recommend you locate the
article.

Problem with a lot of the phone stuff is getting access to the chips pins
for programming
(if they had them in the first place).
Chips are factory programmed and not reprogrammable.

No, they are made by Hammond Co. in Canada and purchased through the Newark Catalog. They are excellent steel cabinets and quite heavy. I have made some cabinets in the past, but nothing as nice as these.

Hi Sven,
The author built a 500V screen supply and a 2700V plate supply.
The magnetic shunts must be driven out using a hammer and a
chisel of about the same size as the shunt.
The author had MOT's with the secondary unconnected to the case.
He did design so if he had to replace a MOT it would work with a
case connected secondary. He mounted the transformers so they were
insulated from everything except the case of the others. The cases were
the center tap.
With the large output capacitor, he designed in a slow start circuit to
prevent damage from large inrush currents trying to charge the cap.

I located an article below that has more info.
I searched " Build a high voltage power supply at low cost QEX"
The author is Randy Henderson WI5W

The worst problem is idle current, 1.2-1.5A on 240VAC, so you should
use the extra space and add 100turns for the primary, and reduce the
idle current to 0.3A. This will also reduce the output voltage below
2kV DC. Many cores are standard E120 types and it isn't worth the
trouble of trying to use the original rubbish

I've planned to bring some information on
http://home.online.no/~la8ak/d4.htm , but haven't translated it into
English yet

Its easier than you think to make these little cabinets. My "woodshop" consists of a clear area on the floor in the shack where I can sit and do small-scale woodworking. Woodshop machinery includes a cheapo Black and Decker sabre saw, and a cheapo Craftsman (or whatever lasts more than 90 days) finishing sander. Recently I upgraded to a little Micromark hobby-sized table saw and a small Skil belt sander for convenience. Hey, who needs a good saw if you have a good belt sander?!?

I won't be making any kitchen cabinets or furniture with this setup unless its for dollhouses!

I really like the idea of an FPGA based spectrum analyzer. I have been
planning to put one together for a while and have started on
schematics. Rather than doing VGA output I am using USB to a PC. I
have the FPGA/DSP board up and running.

It will probably be some form of a dual conversion design with the
input signal being upconverted to an IF around 2GHz and then fed to a
quadrature demodulator.

One other really nice thing that can be done with a FPGA easily is a
Arbitrary waveform generator using block rams as a lookup table.

Hello:
I have a problem with my ts140s. After 3 year of inactivity i power up my all transceiver and it stay 1 month powered but not transmiting. after that i note:
-when i rotate the know down slowly the frecuency goes up 1.9 khz per step.
- when i rotate the knob down fast the frecuency goes down ok (fast).
- when i rotate the knob up slowly the frecuency goes up ok (0.1 khz up).
- when i rotate the knob up fast it works ok.

I reset the microprocesor but the bug don´t fix.
Any idea about the problem???.
Many thanks an 73.

Does the TS 140S have a "button type battery" to power memory circuits
for the CPU? If so, maybe it needs to be replaced. If it does and you
replace it, remember to reset the CPU after replacing the battery...

No, I cant tell you whats wrong. You need to get a service manual, and a cro, and have a look for it - starting at the output of the dial generator and going from there. Maybe someone else has seen this exact fault before, and can say which $.00 part to replace.

Ha. That's takes me right back to '66.

I was so keen to put the radio together I did not bother with understanding
resistor colour codes, I just banged anything in for the resistors. Then
one of the electroylitics went "Bang!". Happy days.

Hello,

Use 10K resistors instead of 100K resistors and be sure to include a fat
Capacitor from the midpoint to ground. Then tie the ground end of the 10k
resistor on pin 3 and pin 5 to the junction of the resistor divider and cap.
(do not tie it to pin 3 directly). Should work with limited dynamic range.

Regards,
Pete

I have a Transmitter which is rack mounted in a cabinet and capable of over 150 watts but will dead key transmit at 120 watts (continuous). The transmit is variable from 5 watts to 120 watts. I also have a dual Receiver rack mounted in a cabinet. Both have power supplies and are very heavy duty pieces of equipment. Wouldn't take much to convert to a 440 repeater or use as is for volunteer fire department or small city.
Units must be picked up in Dallas.Comes complete with manuals for both.
Will sell (make offer) or trade for good Ham HF rig, or ????.

Pictures of manual & rig:
http://www.grodgers.com/dfwforsale/transmitter440.jpg
http://www.grodgers.com/dfwforsale/receiver440.jpg

Units are skid mounted and virtually unused. Appereantly this was a backup unit.

Contact me at ke5bfa@comcast.net or reply to this email.

I doubt that requiring applicants to demonstrate knowledge of electronics would work anymore. I believe that most Radio Shacks start people at minimum wage plus commisions on cell phones, extended warranties, etc., so when that's the 'deal' you're looking at, a would-be employee can do just as well working at many other stores that don't require any particular knowledge of what it is, exactly, that the store is selling.

Personally, I think you could run many stores with, say, 2/3 the people and pay them 3/2 as much as normal and thereby demand some actual skills and retain them (and work 3/2 as hard!), but unfortunately that doesn't seem to be the standard business strategy these days.

I know this is an old thread, but I have a related question:

Quite a few people are building their own PC cases these days--
for example, http://www.mini-itx.com (follow the links on the right side
of the page).

As far as I can see, none of these has *any* RF shielding at all. And I
have yet to hear of them causing any problems (these are not ham radio
operators). The only RF problems I've heard of recently (with consumer
electronics) are microwave ovens interfering with some kinds of cordless
phones.

I'm thinking maybe the only kind of RFI "the masses" are worried about
is TV, and they all have cable...

So I'm thinking of building a computer case for a specific use, and
I'm wondering if I should bother to worry about shielding (evidence
suggests maybe not).

My first thought was aluminum foil, but aluminum forms a non-conductive
oxide, and I don't know if it would ground reliably (not to mention the
"tinfoil hat" jokes). My second thought was copper foil from
http://www.onlinemetals.com (around $.98/sq ft, but shipping adds quite
a bit).

Any comments?

PS:
I like this one:
http://www.mini-itx.com/projects/cardboardcube/

What are you worried about? Ham and short wave fans have a legit
issue, and I guess people doing *very* high quality audio do also.

If you don't fit in a special catagory try taking the top of a
standard PC and hold an AM and an FM radio right next to the running
PC and listen for the noise. You won't hear much. Try it again with
the lid on.

PC cases are built to FCC and European specs for radio emissions. They
are fairly tightly sealed.

The vast amount of emmisions that *do* come out go over all the wires
connected to the PC.

Pick up an ARRL handboox about sheilding and RF interferance
if you want to learn more.

Heheheh. My take on that was to figure that all those resistors and caps in a 2 stage AF amp were not really needed to make it work, they just made it work *better*. So.....I ended up building a 2 stage direct coupled amp before I even knew what direct coupled was......till one of the transistors got so hot >it< went BANG!
--Sigh-- To recapture some of that wide eyed "Will it work!?" Do kids even think that way today? My experience says no. :(

Um, as I recall, 1 billion is 1000 million (in the USA where Radio Shack
is). So that would be 50/1000 or 5% profit.

Source record: 17456

Hi All,

My HP8558B has developed a fault. Could anyone advise?

Up to about 4MHz the sweep consists of a distorted 0MHz peak then a sloping, noise-free, baseline. Above 4MHz the analyser works fine At a Reference Level switch setting of -30dB there is about one division of noise nad signal appear as expected

The distortion of the 0MHz peak and the slope of the 0 to 4MHz section of the sweep varies with the setting of the Reference Level Switch but the actual gain settings seem to be correct, once you are above 4MHz. Also odd single spikes appear in this region at different Ref Level settings

Anything else you need to know?

TIA

John

This is a dumb question, but I have to ask.....does this only show up at the wider I.F. bandwidth settings? If so, this is normal. Do you have the sweep set to automatic or manual mode? If you have your sweep set to manual mode and your sweep is set too fast, this can occur.

HamPoll is here in order to give amateurs a chance to speak for themselves, and in time to provide reasonably accurate and significant polling data on a variety of issues related to the amateur radio service.

You are welcome to browse the polling data we have, but we especially encourage US amateurs visiting here to register with thier callsign and vote in the HamPoll Polling Station.

Whether you come to browse, to discuss or submit new polls, or to tender your vote, be sure to visit regularly as new polls are included from time to time, and the poll data changes as more hams participate day to day.

I associate a .com web site extension as having a commercial, for-profit purpose. Asking for people to register and leave information about personal preferences makes it look an awful lot like you're collecting data to sell for marketing purposes. If that's not the purpose of your commercial enterprise, I suggest that you state clearly what the purpose is, how you make your money, and why people need to register in order to leave their opinions. If it's a non-profit enterprise, I suggest you get an .org extension, and clearly state on the site that it's not for profit.

The Glenayre Power Supply I got with it's companion Amp uses 180A Powerpole Connectors for the 28 vdc output. Anyone got a spare couple of these beasties ?? Even better would be the interconnecting power cable, there are two ~1/4" pins for the +DC and two ~1/4" jacks for the -DC. I found a GR double plug fits the -DC, but the +DC has me stumped. I hate to tack solder a lead on them (too tacky !!).

I have built a few dozen regen receivers and they all seem to work well enough on AM signals--some extremely well--but kind of fall apart when it comes to STABLE reception of CW and SSB.

Has anyone ever built a solid state regen that does well with CW and SSB? If so I would love to know how you did it (I'd even share my some of my massive collection of radio parts with you)...before I go off and build another dozen regens.

I have a box full of prototypes affectionately dubbed my radio reject graveyard (or dead radio pile)...I just don't want to be up to my neck in more prototypes before I finally get a good one.

Seriously thinking of skipping it and building a simple DC or superhet.

I don't know. But for much of their life, they have been treated as
simple receivers. First in the twenties or so, when things were expensive
so it was as minimal as possible. In more recent decades, because they
were seen as a beginner item, an alternative to a complicated superhet.

Simple is bound to mean tradeoffs. Realistically they are oscillators,
yet how often is the care put into them that someone puts into a
free running oscillator? A thick piece of wire for the coil, built
really strong to avoid microphonics, with temperature compensating
capacitors and voltage regulation, just like in a vfo. Add a stage
of isolation between the antenna and the detector, just as you'd
isolate a vfo from it's load. Bypass it will, instead of saving
money by having only one capacitor. Use a good sturdy variable capacitor,
rather than the one you got out of the AM portable.

If you built an oscillator like most regens are built, would you
expect much stability?

One of the neat things about solid state is that the cost of
extra active components is virtually nill, in terms of actual price
and in terms of space. You're not blowing the food budget to
buy that single tube so you can try out the receiver you built.

Look at Charles Kitchins work. Unlike when solid state
first came along, he went back to the basics, read up on the
early articles about regeneration, and then proceeded to try
to make them better in solid state form. So you see that extra
stage to isolate the detector from the antenna. You see a voltage
regulator. And it will still be cheaper than that single tube

receiver in the old days.

I've never built a regen, but the things he puts in his receivers were things I had been thinking about if I'd wanted to build a good regen.

I am looking for the Black (Nylon,Polythene ???) tubing around 6mm OD
and wall thickness of 1mm for construction of 900 MHz whip antenna.
It needs to be fairly rigid as it is glued to an SMA plug.

If anyone can advise what material is typically used and where I could
purchase
a reel of it (maybe it is even pressure tubing for pnuematics ?), it would
be much
appreciated. Australian source would be preferrable.

Thank in advance

Regards

David

I'm not worried about anything specific, but I know the manufacturers go to great lengths to pass an rfi test, and yet it seems they are solving a non-problem.

I do occasionally run PCs with the covers off, but I seldom have a radio or TV on, so if I were causing any interference anywhere (eg in the apartment nextdoor) I wouldn't notice it. I've heard urban legends about early microcomputers causing interference, were they noisier or were old TVs more sensitive to it?

I would have no problem spending money on a commercially made case, if I could find one I liked. IMHO, they all suck. Flashy plastic and poor access even with all the covers off (I didn't consider rackmount cases because I'd like it to be semi-portable).

I do have one "beige box" here, but I seldom open that one, so I don't care how awkward it is to mount stuff in it. The other one I frequently swap out components and I want one that gives me better access with the covers off. I'm considering a "semi-monocoque" design with no frame.

Figure out how to make a stable oscillator at the frequency you are
interested in. Then convert that design
to a regen. I think that is as close as you will get.

Nothing to be sorry about.

Anonymous polling does not return accurate results. Instead you get:

Poll stuffing.
SPAMBOT polling.
multiple votes from sicko clowns.
various other forms of cheating that add up to bogus results.

The guys who would only vote anonymous are no big loss. We don't feel bad about our missing your anonymous vote - and neither should you... Anonymous votes are worse than useless.

Registration before voting is fairly universal around the world - in relation to voting activity that is of any significance. If you want your vote to count and are not ashamed of your own opinion, you should have no trouble registering to vote in our polls.

Did you see any ads there at HamPoll, Einstien?

We do not hold ourselves responsible for the associations that pop up in
some people's minds from time to time. - They've got a million of them, and
who could keep up with them all? (Or give a hoot)

If you are convinced that HamPoll.Com is part of some kind of commercial
conspiracy, your best bet would be to move on, go find something else to
wring your hands over.

Charles , Whatever your objectives with this web site , I shall NEVER
participate ,registered or non-registered ,because I find this type of
polling a useless activity , it is doing something just for the sake of
doing ,without having any positive / constructive end result, it is just
taking up bandwidth.

Mal,

I cannot see on the web page where they mention the material used for the
Whip Radome ?
They also don't seem to sell any tubing.

Can you advise me which page they advertise the tubing ?

Thanks

Try a gardening shop. Drip/micro spray irrigation uses pvc tubing that might
fit your requirement.
Don't forget to do a microwave oven test on the material because some black
plastics are carbon filled.

So when someone makes a suggestion you're going to insult them? If they
don't want to register they're ashamed of something? Out of the many
web site on the internet this is how you solicit participants?

Friendly suggestions: Allow unregistered readers to vote and list how
many voters are registered or not along with your poll data so those
reading the polls can make their own conclusions. Fix your web page so
it doesn't open a new window when I click on 'Forums' (Mozilla Firefox
1.0.6 browser), if I want it opened in a new window or tab I can do that
myself. Keep in mind what associations the majority of potential
readers may make and try to draw the line of what you'll act on and what
you won't not so far over on your side of things. You'll need a lot of
subscribers to get polling that has any statistical significance, I also
suggest you treat people with some basic respect if you want this thing
to get off the ground, Einstein himself may have been eccentric but he
was also polite.

You need us to make this work, so far you haven't shown that we need you
at all.

May be I should not post before the second cup of coffee in the morning, but it seems to me that stable regeneration nets out to a Q-Multiplier. Don't let me discourage your activities, you would not be the first to find a new life for an old method.

Personally, I find myself thinking about Parametric amplifiers a good bit these days...

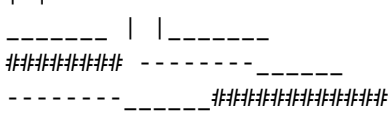
Hi Pete,

1. The sweep is in automatic.

2. The phenomena is as described - 0MHz peak then flat, noiseless, sloping sections - at all bandwidth settings. I see where you're coming from - but I'm not that wet behind the ears! In fact, when you centre the 0MHz peak on the screen, the slope of the noiseless sections either side are the same - i.e., from left to right, the sweep is noise into -4MHz, then a slope DOWNWARDS to just before the 0MHz peak, then the true, quite narrow, 0MHz peak, then a further sloping downwards section to +4MHz - where normal behaviour is resumed. A bit like this (typed, and intended to be views in Plain Text)



Note that this Spectrum Analyser worked well both where I used to work AND for two to three years after I rescued it from the firm's scrap pile and brought it home to my shack - i.e. what it is doing now is definitely NOT what I have been used to it doing!

My guess was that the problem might be overloading due to mixer mis-balance - if all of the mixers are supposed to be balanced, that is. Uncoupling either input to the mixer which converts down from 304 to 21.4MHz gets rid of the 0MHz peak, which I take to be proof that that mixer is balanced, but I've got no test gear covering above 50MHz and so I can't debug the front end of the Analyser.

Does this further info help? I've been told that there are loads of Spectrum Analyser and/or HP experts in this group.

The data is constantly on public display, for anybody to do anything they
want to with.

That makes it kinda hard to sell...

Think it through. - Especially before making ignorant, ugly accusations on
usenet, OM.

I worked for weeks to get the RFI out of my computer. It was coming from within a commerical RFI protected case. I had S-9 plus readings on 40 and 80 meters. When I finally turned my attention to AC power cord and filtered it, levels dropped into the normal band noise.

Early PCs had a lower frequency system clock so there were more
harmonics to beat against other signals to cause interference. The
original IBM PC had a 4.77 MHz system clock that caused all kinds of
problems. There wasn't' a TV channel that didn't have at least one
harmonic, and some had two. The interference dropped off as the
frequency went up, but some early computers could wipe out the upper UHF
TV channels.

3955. Broadband Amplifier

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-24 20:49:39 UTC
From: DPhil <DPhil@breathemail.net>
Message-ID: <430cdcfe_3@mk-nntp-1.news.uk.worldonline.com>
Source record: 17489

I am trying to build the amplifier in W1FB's QRP Notebook, p.135, Fig 4-18
Capacitors C8, C14 & C18 no value is specified, No other broadband
amplifier in this book or EMRFD show a capacitor between collector and
ground. Are these capacitors needed, if so what value and what purpose
do they serve?

TIA

I have an older - but in reasonably decent condition - Radio Shack Regen receiver which does like 590 KC - 30 MHz - operates on 4 "C" batteries and has a jack for external power - bought it at an estate sale. I was able to scrounge up a manual for it too. I've used it a few times, but Regens are not my idea of a good time. Have thought of putting it out to the public for those who like em - but not sure yet if I'll do that. Maybe I'll give it another shot - let it try to earn it's keep. It is small enough, I thought about using it with a QRP transmitter and have a nice portable set up. Maybe I'll try to tune it up per the manual. I hadn't tried that yet - the radio became a back burner project since I bought it. Tuning "may" make a world of difference! Who knows when the thing was last checked or if it was even done right to start with. The thing is kinda neat looking, so would hate to get rid of it. But, if I"m not going to use it, no sense letting it collect

dust.

Not meaning to be rude did you read the caption below the schematic?

Extracted text for those that do not have the book:
"..C8, C14 and C18 are shown only as optional units if it is desired
to roll off the high frequency response for a special application."

That should be enough explanation.

Allison

There's a good article in Jan/Feb 2004 QEX by WD5HOH for A Cascade Regenerative Receiver with two regen stages. The article covers what must be done to achieve stability with references to other regen articles.

3973. The Perfect Ham Store?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-25 22:19:49 UTC
From: eternalsquire@comcast.net
Message-ID: <1125008389.118793.289820@g14g2000cwa.googlegroups.com>
Source record: 17356

All,

I know this sounds like a troll, but it is not, I assure you. I am at a point where I may be forced to consider a career change. My wife wants to teach at a reservation for the next several years, and as I do not see very many days left in my 20 odd-year career as a software designer, I am very much tempted to take her up on this.

Since I have a had an abiding interest in building amateur gear from parts, and since I hear a lot of complaints on this group about certain retail chains not being responsive to amateurs, I thought I should do a little bit of "market research" and ask my potential customers what they might want to see from my store if I should start one.

I know that I can't be all things to all people, and I also know from Idiots Guide to Starting a Business that retail sales can be a tough row to hoe.

My few advantages are that I would (hopefully) thoroughly know my product, that I would be organized where a lot of scrap shops aren't, that I would listen to what the customer wants, and that I wouldn't be going into this simply for sentimental reasons but hopefully to make a small profit to supplement my wife's earnings

So, what is the perfect homebrewer store for you all?

1) Lots of discretes at low prices?
2) Transceiver and other kits sold at slight markup?
3) Parts kits and boards for successful homebrew designs found on the net?
4) A depot to drop off and buy antique gear and test equipment?
5) Home-made precision such as crystal filters, diode mixers, amplifier modules?

Anything I haven't thought of?

Thanks,

The Eternal Squire

Have you considered military/industry surplus/salvage along the lines of
Fair Radio Sales in Ohio or Skycraft Parts in Florida? I can't speak for
Fair but Skycraft turns in a very handsome profit six days a week year after
year and they are always crowded with patrons from kids building a crystal
set to aerospace engineers. There are breaks for a salvage operation as
well. Maybe it would be worth you while to visit them.

Ok.... you asked for it... lol
New hams and lots of us OT's have been frustrated at the hodge podge
arrangement of radios and accessories. Why the new person always asks
is what should I buy..... The ad's and tech info on the products need to
have a "boiled" down list of what it takes to make it all work. i.e.
examples
of radio antenna match need? Power supply? key? mic? Amp? Vertical ?
Slope?
dipole? random wire. Play radio only at home or in car too. Poor lids.
:-(and the whole
works for recommended uses like DX or contest or just rag chew.
Maybe several "typical STATION set ups for a few ranges of total cost"
Even for an OT you just cant tell from the ad's what it's going to cost in
the end
or what it will do or not do very well.

Hope your career lasts a while... seeing all the sw jobs going over seas
just
like the mfg jobs have. Hope they plan to sell the products over seas...
no one here will have a job/money to buy it.

Load Accumulator what? Which mag core ? tube! Reset!!!!
Sure ain't C or what ever else has come along in the last 10 years
since I got to retire and play with my toys. LOL

A straight key is the one for the ignition huh?

Good luck 73 K4TWO

A good Elmer list of hams who can show off their stations
and be able to "guide" a new person into the hobby without
going broke and with enough knowledge that what ever the
Elmer is showing has taken a good while to accumulate.
What ever station you build... its never right forever so it is a
life time job of rebuilding the new station for the new
and varied aspects of ham radio. Even the ARRL
handbook is an accumulation of many folks efforts.
Ham Radio is just TOO big to be a master of all
the hobby. (although some declare that they are LOL)

I didn't have an Elmer so many years back as a
novice, I was pizzzed off for 2 years before I learned
that DX didn't live in my novice band.

P.S. Make it all free, won't last long but be big hit.

You do plan on a web site eh? I have bought most of
my recent "ham stuff" on ebay or other places on the web.
By the time I spend gas and time shopping or going to
hamfests, I can have the same items shipped the next day.
Just won four 50mhz crystal mobile rigs for $6 costs more
to ship them than the purchase fee from ebay auction. But
look out 6m here I come. Tune Tweek Diddle Diddle smoke.
I need a big garage.

Need good pictures / prices and web site to sell these days.
Most commercial places are too cheap (price fixing?) to put
prices in mag' advert's and web advert's some dont even
put an email address up due to spam and customers that
are unhappy.

Yeah, I got my rag chew award a long time back lol

A copy of an email I sent to the ARRL recently below:>>>>

ALL the files and adverts I see in QST or on the web can drowned and
overwhelm a new ham.
What is ALWAYS missing is "what this radio needs to work is.... AC line...
DC power supply... Antenna match... Types of Antennas a user might connect.
Sheeez get some of the basics out to the "New Hams" they want to sell
these things too.
Let them know about how much MORE it is going to cost than the listed price
of the current unit under test.
How about a Key or Speaker or Mic, need a rotor?.... Come on lets get the
newbies a chance to spend his few dollars with out getting
a box and then wish for Christmas to come so he/she can connect it up and
really get on the air.
Go look at the advert's and "reviews" as though you were NEW to the hobby
and about to invest some hard earned money.
While most of the tech info can be impressive, it is fluff to a newbie.
Just tell me how it worked and what needed to make it usable.
How much were all those "options they said were available?" Money for what
filter? What warrantee??? It is the price of a car is it 5 years too?
Thanks.... Hope this message gets to where it will do some good.
Might even put some "shop and compare tables" out for them.
I been around a long time and was getting ready to upgrade from my GTX757II
to a "last good radio" for my retired years and wading through
all the poo has just about put me off buying another radio. I did apply
for a new 4 land call for retired call... I hope Vanity call. Can get a
little vain when that's all that is left. hihi
I just spent 2 days rebuilding the optical dial that froze up in my 757 so I
better move on before it gets arthritis again.
Now WHAT to buy?? eh

You do realize that for some reason people like to gripe about Radio
Shack. They have contempt for the place, while all the while expecting
it to deal with them.

Radio Shack hasn't been a main place to buy parts since a few years after
Tandy bought it in the sixties. Selection was/is limited and prices high.
They were a great place to get something quick, because a store would likely
be nearby, and a place to get them in the off hours.

But just because people like to gripe about Radio Shack doesn't mean
a thing about the state of buying parts generally. Note they are griping
at one store, not talking about other places.

There are plenty of places to buy parts. Sadly they may not be in a cluster
downtown in your city, which was the case decades ago. But they still
exist. Some places have risen up to deal with specialty items, filling
a void that is missing. Amidon is a classic example, starting at a time
when toroids were virtually unknown, and being the standard for buying
the cores in small quantities (be it the hobbyist or the prototyper).

So you really need to not be looking at the griping at Radio Shack,
or Radio Shack itself, but at what exists today and whether it
can fill the market, or if there are gaps that need filling.

My opinion, the easist way to profit is by unique product development and marketing, or in the service sector. I just can't see making a living in amateur radio retail... the competition is stiff and the profit margins are small.

You are a software developer? I suggest you use your talents to develop something in the amateur software area. Can't off hand suggest more specifically, but digital radio, digital voice, and even video are areas one might look into. Then there are the other peripheral products like logging, QSL, maps, world time and geographical info, radio control, propagation info, antenna measurement, etc, and a whole lot more I can't even think of at the moment.. Good luck.

You do great photo work as well Bill, that's the sharpest image I think I've I've ever seen on QRZ. Can almost see where you're tuned to! Looking forward to finding you on the bands again, will certainly recoignize the call next time instead of trying to think of where I've heard it before.

My modified IYH MRF-150's are alive and doing well, been a couple years now, so I think they're in for the long haul. How do you operate without a monitorscope? Mine is on whenever the rig is on. Instant reminder when I've forgotten which antenna is selected and the like. (Haven't yet modified my little STAR to automate that process like I had on my Signal One.)

Regards
W4ZCB

I have a new Sony digital camera 7.2 megapixel that I have been slowly learning how to use. I shoot pix using a tripod and max megapixel (20 megabytes), then I use a program that creates an optimum JPEG file that QRZ.com prefers that is a little less than 500 kilobytes. I use an external diffused flash that works quite well, attached to the Sony. I can shoot a dozen pix and delete all but the one I want (at no cost for film and developing).

My push pull MRF150 PA has been faultless for more than 4 years. I clean out the dust occasionally. The protection circuits all work quite well. Ameritron has a new 600 W PA that uses 4 MRF150s. I don't want to live that dangerously. My ancient 30L-1 works beautifully at 600 W. At 800 W it starts to deteriorate, so just 1.25 dB of ALC keeps it happy.

The 572B tubes are Chinese from RF Parts in L.A., but they use American made thoriated tungsten filaments and seem to be quite reliable when not abused. A matched quad costs about $200.

I have everything I need to keep everything working OK but I don't need to keep it all connected all the time.

> they might want to see from my store if I should start one.

Of course, market guidance is a good thing, but keep in mind that this
newsgroup is probably far from representative.

> So, what is the perfect homebrewer store for you all?

DigiKey, with some RF parts added.

> 1) Lots of discretes at low prices?

There are lots of places to get discretes. This is no longer the problem it
used to be. The problem is getting them at a local store. RS used to fill
that bill, and there used to be a number of local electronics retailers.
But to tap that market, you need to be everywhere. In a market large enough
to justify that sort of presence, there are already competitors.

> 2) Transceiver and other kits sold at slight markup?

What can you offer that AES and the like can't? Unfortunately, I think a
lot of stores suffer from spending time helping folks understand the
products, only to have the customer go get it at Texas Towers for five bucks
less. Hams are cheap. If you are going to sell transceivers you gotta be
near the lowest price. Now maybe a wide range of kits might be a market
with little competition.

> 3) Parts kits and boards for successful homebrew designs found on the
> net?

There are a lot more homebrew possibilities out there than there are kits,
but that is a pretty low margin market. Still, I wonder if something simple
like providing parts kits for FAR Circuits boards might not be a
possibility. Provide a needed service and keep your costs down by
leveraging someone else's board mill.

> 4) A depot to drop off and buy antique gear and test equipment?

Again, you need to be everywhere. If your wife plans on working on a
reservation, it sounds like the place you will be might be a pretty small
market.

> 5) Home-made precision such as crystal filters, diode mixers, amplifier
> modules?

Filters might work. Mixers, amps etc are already available from Minicircuits. But filters for common homebrew IFs might be a market.

> Anything I haven't thought of?

One thing that occurs to me is that almost any project nowadays involves a microcontroller of some type, typically a PIC or AVR. Even though programmers are trivial to build, the need for a programmed micro is a show stopper for a lot of potential builders. That might make an interesting niche.

Take a look at the successful guys.

DigiKey has almost a half million SKUs. Although they are shy on RF parts, for almost anything else you want they are gonna have it. They have a fabulous search facility on their website and the best customer service on the planet. Their prices might not be the best, but they make up for it by being terribly easy to deal with.

AES is an expert at lightening your wallet. Their prices are pretty low, when you call them you will talk to someone who knows what it is you want. And the next day the rig shows up on your doorstep. Simple, painless, and close to the lowest price.

Ever call International Crystal for a crystal? Their prices may be high, but they will make sure you get exactly what you need. If you have a commercial radio, no matter how obscure, they know what kind of crystal it takes. Doing something weird? Tell them about your circuit. They are dedicated to getting you what you need.

If you are going to be out in the boondocks, like it sounds, then you need something you can do online. The good news is that is relatively cheap. The bad news is that now you are competing with an entire planet full of competitors, so you need to come up with something really unique.

..

Source record: 17374

Sage advice!

"If you are going to be out in the boondocks, like it sounds, then you need
something you can do online."

Not totally boondocks. The place where my wife will be working can be seen from the Interstate. All along the Interstate for bunches and bunches of miles can be seen places where one can get souveniers and inexpensive Native jewelery and other handicrafts. Along roads in all directions for hundreds of miles are signs leading to these various places.

I have been tempted to try some type of Doctor Demento theme type technological curiosity shop stocked with ham kits, gear, and license guides, as well Jacob's Ladders, black light lamps, crystal sets, and introductory science stuff for the pre-teens... it might fit right in with the rest of the tourist trap area but I'm really uncertain I want to completely take my chances on it.

"The good news is that is relatively cheap. The bad news is that now you are competing with an entire planet full of
competitors, so you need to come up with something really unique."

Ah, yes, the perils of globalization, which caused what I do best to be offshored in the first place. This is kidding: now its a contest between one expensive genius versus a planetfull of poorly paid geniuses working for a multinational. The latter will win every time.

At least I won't be too bored reversing roles with my wife for the next couple years:

While I wait for my ham customers to drive in, I could do software and/or hardware R&D.

The IF idea sounds definitely good.

More ideas, anyone?

I couldn't find the 1276 manual listed on MFJ's website, either.
However, if it were me, I'd either call their 800 number, or email them
with the question. They are very good at responding.

I was reading the responses to your post when a thought prompted me to add another comment. The electronics market for the amateur in Japan is exceedingly more developed that what it is here in the US. Every now and then I hear of interesting amateur equipment, electronics devices and parts that, for some reason, are not available in the US---I sure would like to have one of those Sony automobile receivers with short-wave. Heaven knows what they have for the computer hobbyist. Possibly, an import operation of sort can fill the void---an interesting niche.

For the life of me I can't remember what part of Tokyo the famous electronics district is in.

Maybe I shouldn't have posted this---the idea sounds good to me too.

Tom,

The district in question is the Ahikhabara (sp?). From what I have heard and read it is the largest elex flea-market in the world.

There is also the possibility that we could import discretes and other parts directly from small shops in India and China.

The only problem is that it seems that US Customs import duties for electronics coming in from Japan are rather punitive to small-time operators. Maybe I am wrong.

Maybe you and I should go into this one together :)

3996. A Weekly F.A.Q. - What Is Ham Radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-26 18:56:13 UTC
From: Polymath <aiyr.r.bean@lycos.co.uk>
Message-ID: <1125082573.078138.29130@g47g2000cwa.googlegroups.com>
Source record: 17379
Cross-posted to: rec.radio.amateur.policy,rec.radio.amateur.homebrew,uk.radio.amateur

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

I do not wholely agree.

There are many radio amateurs who are, or have been, professional engineers, not necessarily radio engineers, who contribute in their many various ways towards the hobby.

'Hobby' is perhaps not the best of descriptions. It is an international affair.

The civilised Japanese, technologically and socially, are much in advance of the so-called western democracies, excepting perhaps the Scandinavians. The Chinese and Indians are very rapidly catching up.

In the meantime, the well-armed Americans are slowly descending into civil war.

Assume the center is a zero frequency. Looks suspiciously like LO IF overload to me. Try a 10 dB pad in the mixer output -- should be easy to get at. As you mentioned there may be a mixer balance problem. I thought the HP8558B used to plug in a HP141T display, but found a pic on the web, and it appears to be a later generation. I have occasionally seen the results of transmitting directly into those old spectrum analyzers, and in the 70s, it was $1,000 for the attenuator, and $1,000 for the mixer. Sure hope you don't have that kind of problem.

Regards,

Frank

In Britain there are few 1 man or family companies selling components.
Have a look at
www.modecomponents.co.uk
www.jabdog.co.uk
www.sycomcomp.co.uk

In western european countries there are a number of traders selling surplus components incl RF parts ,who move from fleamarket to fleamarket ,from country to country. A number buy surplus army kit from eastern europe and sell these as components.....they have done that for many years ,hence must have a reasonable income from these activities .
I have seen a web site related to the sale (auction) of US Government equipment (located in Virginia) with some mouthwatering electronic (test)equipment . There should be a market for this equipment ,even as components.

The marketing question remains : Is there a substantial ham homebrew market in the USA . How many of the approx 700000 licenced Hams in the USA purchase electronic components on a more or less regular basis ?

Surplus people in the USA like 'Surplus of Nebraska ' and 'Peter Dahl' seem rather expensive.

Let's stick to topic, we can organize the offshored labor union
later...

I want to know what hams really want when they go out to buy stuff, as
an initial guess I am willing to listen to what they say they want.

The Eternal Squire

Yes, but others like ALL Electronics and MECI are quite inexpensive... except that they aren't configured to sell to hams exclusively.

I think part of the answer might be to look at the offshoring problem in reverse... Our manufacturing has been offshored for 20 years or more, backoffice has been offshored for 10 years or more, and software has been offshored for about 5 years....

So, other countries are creating discretes and subassemblies to place into entertainment, consumer, gaming, and white goods... with only a nod give to RF. Fortunately, many discretes being sold for above purposes could be used for ham purposes with some ingenuity, we do it all the time!

What I think we need to do is buy cheap components from offshore and sell at slight markup, that implies finding sources direct from India, China, Korea, etc. Japan is more a consumer than a manufacturer.

Maybe instead of a store we need to start a buying club?

On the individual/personal level,
for a great many of us it IS a hobby.

Strictly speaking, however, amateur radio is, by FCC
rules definition, a service.

Cheers,
Bill K2UNK

Two issues:

A) I think in order to deal with the Akihabara we are going to need at least 2 more things: 1) a Japanese ham willing to buy for us, and 2) a US Customs broker or equivalent.

B) We still don't know our target market. Would it be consumer equipment, ham equipment, rf subassemblies, or discretes? Remember, the lower the integration, the less up-front investment in inventory would be required.

C) If this was such a desireable thing to do, why hasn't it been done before?

I would not rule out the possibility of being able to grow a market that
doesn't currently exist.

I think a significant number of hams don't homebrew not because they
don't want to -- but because it's difficult to find parts.

Make part shopping easy, and you could make customers of people who
aren't buying from *anyone* right now.

Then again, you could also lose your shirt<grin>.

I suppose we could use Drake's Law: I'd estimate that perhaps only 1 in 10 Hams are interested in homebrewing, 1 in 10 have the skill, and 1 in 10 have the means to stock up a large parts library: basically an interested audience of 1 in 1000 hams, meaning an audience of no more than 700 hardcore homebrewers. Can that be right, only 700 of us potentially on this newsgroup?

Although, if I provide the service of the homebrewer's parts library: reasonable price, fast shipment, good ranges of discretes for 160-6 M construction, then I could address up to 7000 hams who have both the interest and skill who don't want to kit but do want to try something new.

If I bundle the parts kits with the FAR boards, I suppose I could address the 1-3 additional people on the bottom end of the skill scale. Now we have an audience of up to 21000 hams, a nice healthy audience.

If only one of 100 hams in the kit audience buys a kit per year, then I have only 210 sales per year. If the average parts kit cost me $50 and I mark it up by $5 I only make about $1 of profit per kit after taxes and expenses. 210 sales per year X $1 per kit is $210 per year. Not good!

Or are there things of which I am not considering.

Yawn,

The Eternal Squire

FYI:

I was watching the "US Government" site a while and found the auctions
exceeded anything I would call a "deal on equipment"
The site is http://www.govliquidation.com/index.html
I don't know how it would work for an overseas buyer though,

Source record: 17395

I got a HP141T with 8554B and 8552B plugins.

After replacing some transistors and fuses in the powersupply, I decided on a careful power up with a Variac

There is some light on the CRT and a horizontal sweep at the top of the screen (I suppose the picture is out of alignment because of the incorrect voltages)

It turns out that the ribbon cable to the CRT anode and storage electrodes is split open and arching between 2 wires, even without the full mains power applied.

Any suggestings on:

Where to get a new cable?
How to repair them?
How to remove the CRT, as this is not mentioned in the service manual I downloaded from BAMA.

Thanks in advance, Wim

I think your chances of a new cable would be zero - and if you did, it would be as old as the original one in there. I suggest you cut out the old cable, and replace with a salvaged length from a scrap monitor/tv set etc. Carefully heat shrink your connections, and cable tie the sections clear of grounds. There is only a few KV there (its a relatively small tube) so flashover shouldnt be a problem. The out of vertical alignment trace could be another issue - but hey, lets deal with the smoke and flames first hi hi

I don't know about "hardcore", but many AmQRP kits sell that many in the
first week. OK, you could say that a kit really isn't homebrew. But there
are a lot of people out there who like to melt solder.

> and expenses. 210 sales per year X $1 per kit is $210 per year. Not

Hi, all concerned:

This one was on ebay a while ago. Bids didn't get past the reserve, and I made an after-auction offer which was accepted.

There was no information on what is inside.

I've gotten as far as turning it on, listening on 40M, and documenting the tube lineup.

Its general form is:

6AK5-6JH8-6JH8-6BJ6 X3-6AQ5, with l-o's, bfo, detectors, agc-amps, S-meter circuitry. The r-f stage has separate peaking. The 1st-lo is tuned by a smoooooth National PW-type drive The second i-f has provisions for 2 switched 9-pin plug-in-style mechanical filters and a "wide" position. Sri -- the filters are long gone. Power supply is internal, with plug-in solid-state
rectifier and a couple of 0B2's. Line cord has one of those fused plugs which
purist-collectors drool over. I don't have a pic of the bottom side; however, it's nicely
homebrewed.

Date codes on the tubes are '50s and '60s. All but two of the shields are those nice ones with dissipators inside.

There are 5-pin plug-in coils for 80-10M, and extra BUD ceramic forms, in a box.

Physically, it is H9"XW12" with tilt built in to the design, and 18" deep. It weighs around 30 lb.

I have the ebay jpg's, which can be emailed to interested
parties.

My original intent was to find an "HBT-XX" homebrew transmitter to go with it, and the intent has fallen by the wayside. Oh, well . . .

$300 plus about $40 for insured ground shipping to conus.

73, and tks for reading.

What about this:

Instead of offering a "stock" of parts or even a "stock" of predefined kitted parts... offer a "part collection service." Someone who wants to build a homebrew project could send you the schematic/article; you would review the requirements and email them a quick quote on what it would cost to provide the parts and the estimated time required. If they approve, and order, you then collect the parts from your own sources: some would be your "stock on hand", some would be orders you place to other suppliers.

Advantage to buyer: one stop shopping; no need to spend hours going over catalogs and going to different suppliers in order to get a pile of parts together for a project. They dream of a project...they end up with a bag-o-parts. It might take a little longer, and be a little more expensive, to get the parts (because you might have to go find some of them); but it will be a "turn key" operation for the buyer.

Advantage to you: You don't have to stock certain predefined "kits" or go to the labor of building kits that might just sit on your shelf for months. All you have to do is keep on hand a good range of basic parts (that you pick up surplus, or on sale, when you can). In other words, just keep a good "junk box" stock for yourself. If the customer needs a part you don't have, then your cost to acquire it, and the delay, can be figured into your quote.

Isn't that what we have going on in Iraq at this very moment?

> users have to purchase ready-made gear. Manufacturers
> are not licensed to operate their gear. Radio Hams
> are qualified to design, build and then
> operate their own pieces of equipment. They do this

A gross (and inaccurate) generalization. A great many hams I've
met in recent years barely remember what Ohm's Law is, let alone how to
do anything resembling design. They do indeed purchase their radios
'off-the-shelf,' talk about the things that matter to them on the air,
however non-technical the subject matter may be, and often show up at
radio club meetings.

And you know what? The vast majority of them are very smart, very
nice people who, while they're very interested in the public-service and
volunteer emergency service aspects of amateur radio, and may have made
significant contributions to the hobby and their community in other
ways, may never have so much as learned how to pick up a soldering
pencil.

Lack of real electronics experience does not make someone with a
ham license any less worthy of respect, Beany, no matter what you may
believe. I say this as an amateur radio license holder for the last 27
years (first as WD6EOS, then later as KC7GR), and as a professional
electronics engineering tech (for just about the same number of years).

And, for the record: Yes, I've been tinkering with electronic and
radio projects for most of my life.

Many have said that amateur radio is a dying hobby. Personally, I don't believe that. However, if there is any grain of truth to such statements, it's not the lack of technical skill in SOME newcomers to the hobby that's hurting the hobby.

What will quickly kill amateur radio will be expressing ongoing disrespect and hostility to those who choose to contribute to the service in non-technical ways. You don't need to know how to use a multimeter or whatever to be a good on-air operator, or to be of value in a disaster situation.

You can continue to post whatever kind of misguided "FAQ" you want to, Beany-boy. It won't change the fact that I, at least, have seen enough of your previous rantings on Usenet over the last few years to know your true colors.

PLONK!

Your Childish Broadcast (CB) below serves to
classify you.

Those whom you mention who are operators but
who are non-technical are the CBers whom I warn
against in the FAQ.

Ham Radio is not about operating - that is CB Radio
including CBers-Masquerading-As-Radio-Hams whom you
repeatedly mention.

I have never "ranted" on the Internet - I have only
posted sincere and genuine concerns about the decline
in Ham Radio by the influx of the very Childish
Broadcasters (CBers) that you typify.

If you have indeed been around for as long as you
claim, then you should know better than to enjoin
an international public forum in the rather
silly and infantile style that you adopted.

Shame on you.

Stupid boy.

Having read this thread, I must agree with the assessment that lowering standards will NOT help Ham Radio. In the USA, the ARRL is doing its best to turn the HF bands into an email forwarding facility, by pushing regulations that will allow PACTOR II and III, used by the PROPRIETARY SCS Modems, and Winlink, across ALL the bands. Soon there will be nothing but robots, relaying email to and from the internet. Anyone who

can get a cereal-box license and is willing to spend $1000+ for the modem, as well as whatever an HF rig will go for, will be able to use the "ARRL HF Internet Service Provider."

John:

How do you figure anyone here is for lowering standards?

We are for bringing standards up-to-date and getting rid of archaic,
seldom used methods and "historic concepts."

No one is for reducing standards... indeed, how could standards fall much
lower than where they exist now? Amateur radio is already decades behind
technology... that should be nothing less than totally obvious--well,
other than to the the totally clueless...

Hello, i would like to add a 500/600w solid state amplifier to my HF station (Kenwood TS870 & Kenwod TS-2000, sometimes Yaesu FT100d), possibly with an automatic antenna tuner.

Yaesu FL-7000 seems to be the best choice for this needs, what do you think about it?

What is the price of a good used?

What's his most weak point to first-check before buying ?

Thank you very much,

Riccardo IK5WQO

AKIHABARA! :-) Fabulous place in Tokyo!

In the early 1950s (!) it was far from a "flea-market" but rather a
collection of hundreds of small shops selling ALL SORTS of radio
and electronic parts, kits, ready-built stuff. Fantastic then.

The best kit I ever put together was a monophonic "high-fidelity"
amplifier with preamp, the preamp box containing a TRF AM receiver
for superb AM reproduction...purchased at a small price by this
then-GI in 1954, assembled, used, sent home and used in the States
for several years.

Akihabara has been written up in lots of electronics magazines,
from Audio Engineering to (I think) all of the U.S. amateur radio
periodicals. From talking to others in-person who had visited it
in 1970s and 1980s, it is well-worth a look-see for anyone who
gets to Tokyo, Japan.

Having controlled my "megapixel jealousy," let me suggest a very
easy field-expedient extreme close-up adapter: An ordinary large
magnifying glass. :-)

With an LCD screen now the optical viewfinder replacement on
cameras, a magnifying glass held in front of the lens can be
positioned easily for focus, even with the auto-focus varieties.
It can get in there very close for detail shots of the ever-
shrinking size of modern electronic components. I've used a 4"
diameter office type of magnifier glass with great successs on
close-ups using a Panasonic auto-focus digital camera,
magnifier held in the hand.

Many of the pc power supplies used in the clones
have minimal or no filtering inside them,
once they get the contracts, they strip them down,
eliminate filters and add jumpers to them.

4028. FT-1000D - 4th IF notch & prod det - frequencies? function?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-08-28 02:14:06 UTC
From: ka9s@arrl.net
Message-ID: <1125195246.661927.198090@g14g2000cwa.googlegroups.com>
Source record: 17311

I would like to understand the frequency scheme of the 4th mixer, 4th IF / notch filter, and product detector of my FT-1000D. I would also like to know how these stages function. I bought my FT-1000D in 1992 and it is still my main/most modern rig. It's a workhorse and I appreciate that.

I have the Yaesu FT-1000 Technical Supplement document. It's thick, heavy, and full of good information. But it is totally lacking in any sort of functional description of the rig. I had been spoiled with American boat anchor documentation like Drake and Hammarlund. They go to great lengths to describe the function of each circuit in their rigs. Yaesu acts like it's some great secret, or puzzle to figure out.

Here is what I have surmised so far:

The four local oscillator injection sources are centralized on one circuit board they call the "Local Unit". This makes sense as they have to coordinate the frequency shift of some injection oscillators to realize the IF shift and variable width functions. It's the fourth IF, notch filter, and product detector that are not obvious to reverse engineer. I have surmised the following frequencies:

1st LO - 73.63MHz - 103.62 MHZ (hi side injection to correspond with the tuning range of 100 KHz - 30 MHz).

1st IF - 73.62 MHZ (roofing filter).

2nd LO - 65.405 MHz +- 1.5 KHz (low side injection +- shift / width).

2nd IF - 8.215 MHz (first set of filters)

3rd LO - 8.67112 MHZ +- 1.5 KHz (hi side injection +- shift / width).

3rd IF - 455 KHz (second set of filters)

4th LO - 12.635 MHZ ? (High side injection?)

4th IF - 12.18 MHz? (It seems that this IF exists only to add the LC notch filter).

Product detector oscillator - 12.18 MHZ?

It looks like the LC circuit of the notch filter is fixed in frequency. It seems that the "tuning" of the notch is accomplished by IF shifting the 4th IF. There is an oscillator on the IF Unit (Q 2056). It has two crystals (X2002 - 12.280 MHz, and X2003 - 12.283

MHz). I am guessing one or the other crystal is active based on the rig being in USB or LSB. This oscillator is "pulled" in frequency by a varicap diode D 2080 and the front panel variable resistor "Notch" VR 8901-1. This oscillator seems to be mixed with the 4th LO though I can't figure any mixer product that makes sense to me.

The choice of 12.18 MHZ for the 4th IF and notch filter seem poor at best. (I had to reverse engineer this frequency value as it is not documented anywhere I could find.) The achievable Q of a LC notch at 12.18 MHz is going to leave the notch fairly wide (and it is - a crappy notch compared to my Drake R-4C - why bother?). Why they didn't use the 455 KHz IF to implement the LC notch and leave the receiver a triple conversion design is a puzzle to me.

It seems that the injection signal for the product detector does not come from the Local Unit. There is an oscillator Q 3002 with the crystal X 3001 - 12.18 MHZ on the AF Unit board.

Am I even close with this explanation of the 4th IF / notch and product detector? Can anyone explain how this is actually working? Is there any way to make the notch filter narrower / deeper?

Expert insights always welcome.

But then again, I dropped a zero because I was so tired writing the letter. Would be 2100 sales per year, not 210. With 1$ net profit margin on a $50 sale, that would be $2100 per year.

Because unless I know different from an authoritative source, US Customs pretty much considers anything much above a transistor to be military dual-use tech in the post 9/11 era. Take a look at the Ebay ads these days... you'll hardly ever see a US Ebay willing to sell outside CONUS due to export hassles.

Importing is almost as bad... Outside of NAFTA or CAFTA expect pay to duties in excess of 12 to 50 percent above your $400 annual exemption for gift items.

I've updated my web site and added some new homebrew content.

http://www.qsl.net/n2cqr/

I've also included info on a new PODCAST program on homebrewing that Mike, KL7R, and I have put together. It is called SolderSmoke and I think it will be of interest to members of these groups. Mike (in Juneau) and I (in London) regularly discuss our homebrew projects. We've turned the QSOs into a kind of radio program. You can listen to it via your computer, or you can subscribe and have episodes automatically downloaded to your MP-3 player. Then you can listen to homebrew-oriented QSOs while on your way to work, or wherever.

I hope you like it. Feedback welcome. Here is the URL for the website: http://www.qsl.net/n2cqr/

Hm, that's interesting. I just put a customs declaration on the package like I always have, and haven't had any extra problems since 9/11.

I'll bet a lot of people avoid exporting because of the large number of recipients who beg them to falsify the customs tag to minimize the value or declare it as a gift. It seems that people don't want to pay the high taxes they've imposed on themselves via their nominally democratic governments. Don't hear much complaining about accepting the social services those taxes pay for, though.

Thanks for the info. I'll keep it in mind. My miniature bench vise can hold the glass steady.

My Sony has a built-in zoom feature that works pretty well. The auto-focus works OK, but works better with a little background light.

The savings in film and developing costs is a true breakthrough for an amateur casual photographer like me who needs to do everything at least a dozen times and likes to see the immediate results.

That's true for every hobby or recreational sport.
There's always a minority of enthusiasts (hams, golfers,
you name it) that are extremists.

Cheers,
Bill S.

This is a capital idea. I can only see one little problem: what if the parts list is spread between 3 or 4 vendors and I have to pay $5 handling fee to each vendor? This can get pretty expensive fairly quickly for the customer.

I think that the idea was that you would be able to combine orders from several people per order to each supplier to reduce the overall shipping costs. Also, buying by the standard break saves money, per unit. I have a lot of parts on hand where it was cheaper to order more than I needed because the next break was less than ordering a smaller amount. EX: $1.45 each. $12.50/10 or $100/100 and I needed 85 parts. 85 * $1.25 = $106.25 so I got 15 extra parts, and saved $6.25. I've done a lot of repair jobs over the years with parts I got for "Free" that way.

> reasons but hopefully to make a small profit to
> supplement my wife's earnings

You might want to emphasize "small" in profit. It's unlikely you'll make much more money at this then you would at a minimum-wage job. Of course, you might not like any minimum-wage jobs so you're left with pursuing your hobby and making a few bucks at it too, and that's not bad at all.

If your wife were a specialist doctor to Hollywood stars or a high-paid lawyer then sure, knock yourself out with a home-based business. But she's not gonna be making a lot of money by teaching at a reservation.

> I do not see very many days left in my 20 odd-year career
> as a software designer

Don't knock selling what you already know, there are ways to contract out programming services from anywhere in the world quite easily.

> So, what is the perfect homebrewer store for you all?

I'd say to go for whatever you enjoy the most. If you aren't sure what you like, dip your feet in several pools and see what sells. Others here lament the "good old days" of homebrewing, but as far as I am concerned we're in it right now. Components from 70 years ago till yesterday are on E-bay all the time, and modern parts are available over the web in small quantities quite easily. Anyone is free to mix and match industrial with consumer with military with ham technologies as they choose - and this is exactly what homebrewers were doing 30, 50, 70 years ago as well, except now we have access to so much more of all of it!

Tim.

Unless you do time-exposures (rare), it is possible to hand-hold
the magnifier without blurring or distortion. The LCD is better
than the 35mm SLR through-the-lens viewfinder in my opinion.

>My Sony has a built-in zoom feature that works pretty well. The auto-focus

Most seem to be like that...more light the better. I've used a
20 W halogen-bulb mini desk light from the IKEA store for good
Illumination on small subjects. According to the old Norwood
photo meter it has the same output as a 150 W incandescent
flood at 2 feet. ["over 150 W CW above 300 GHz" - :-)]

>The savings in film and developing costs is a true breakthrough for an
>amateur casual photographer like me who needs to do everything at least a
>dozen times and likes to see the immediate results.

As one who got into "serious" amateur photography in high school
(Class of '51), 35mm route, I have to say it's *FANTASTIC*! :-)

Wife and I got a Panasonic that holds all images on a 3 1/2" floppy
"Super Disk" (over 500 MB) back in 2000. A couple years ago I
started to "take notes" on various projects with that camera, find
it is ideal to show progress, even to show oscilloscope screen
waveforms (tripod or other stable mounting recommended, plus a large
cover cloth to cut out background reflections).

That Panasonic model went off the market but it continues to work
fine. A new Aiptek still/motion-picture we just got cost only a
third of the Panasonic's price; I'm still getting acquainted with
it only two weeks out of the box. Smaller, lighter, it has a
manually-selectable short-range focus capability. The tripod we
use with it (in place of cheap supplied mini-tripod) was bought
by me in NYC in 1952 for use with a Kodak Retina II 35mm range-
finder camera. [sometimes pack-ratting is good :-)]

I do closeups the old-fashioned way with my Digital Rebel,
using an extension tube to hold the lens farther away
from the sensor than it would otherwise sit. With such
gear it's easy to blow up an individual component (or
coax connector, or coin, or whatever) to fill the entire
frame.

Never found any EOS-mount extension tubes, so I use an
EOS-to-M42 adapter and my screwmount Pentax lenses and
extension tubes. The Pentax lenses work really well on
a DSLR for general photography, though you have to run
the camera fully manually when you do.

Tim,

I appreciate the encouragement. It really isn't about the money tho.

The way things are turning out, I am going to be reversing roles with my wife for at least the next few years. I'm actually looking foward to doing this for several reasons:

1) Caring for my baby girl (22 mo) and possibly one other being planned for is going to allow me to lay down the foundation of my children being a lot closer to me by the time they become teenagers.

2) Up where we are going, there is fairly little light pollution. Last time I actually had a chance to see the entire Milky Way was in my mid-20's.

3) I'm essentially an ABD in Computer Science with about 20 broken years experience working from drivers from GUIs to everything inbetween, in 5 languages and 10 platforms, and I'm only 43. There isn't a whole lot I haven't done for either small companies, large ones, or on contract, so it is all starting to become the same....

4) What I'd really like to do is create Open Source tools at a much higher level of quality than I have seen by a lot of sometime authors. I have plenty of ideas and now at least some time every day to think great thoughts that won't be owned by an employer.

5) I got into hardware and software primarly as an escape from an abusive family growing up. After being on antidepressants for 10 years, shrunk to a fare-thee-well, and having a terrific wife and a wonderful girl for my family, my family has become my escape from my work rather than then other way around. This is a good thing, but it is no wonder that I am tired of working for a wage.

6) I am looking forward to doing a lot of homebrewing and a little DX where I don't have to worry about how my antenna looks to the neighbors.

So I really don't know what I want to do. I am learning that being a full time homemaker won't be all scones and cream but that the some time I'll have to be creative will be more than than I had been having in a cube.

Problem is, I don't know just where to start.

The Eternal Squire

I used to do that with my Exacta VX 35mm SLR and
three extra lenses plus the extension tubes (circa 1954
and duty-free store). Problem is the WAIT and
developing fuss (changing bag, loading the developing
tank, timing out the Microdol, etc.). Then one finds
a few frames less than optimum and those have to be
done over. :-(

As Bill Sabin remarked the digital camera lets one
check the image NOW...and (as I love) do it in color.
INSTANT IMAGING. Gotta love it for visual note-taking
as a project goes through its stages.

Not to mention scope photos done directly, economical
given the cost of digital scopes nowadays. No messy
residue from Polaroid packs as they were as late as in
the 1980s. For easy recording of scope settings, just
refocus, reframe and get the whole front panel in a
second shot. Every setting on the scope's front panel
is right there for reference. [the old changing bag
now does double duty as a background-light shield when
taking scope shots, not the best but it is black...]

A packed-with-printer/scanner/whatever digitial image
editing program can size up the digital photos, make
them black-and-white (if desired), size them...and the
result stored in the PC or on CDs (no emulsion
reticulation worries or wrong "color temperature").

==========
That's great . Being a radio amateur you might be in a position to promote
Linux , so that Linux will be increasingly used for amateur radio software.
Perhaps you might do some work for ARRL ,such that in future all Ham Radio
software ARRL are associated with can ALSO be run on a Linux box.
In spite of Linux gaining terrain ,at the moment most Ham Radio software can
only be run on Windoze or DOS .

Is there anything special for APRS vs. regular packet? As far as the TNC, I wouldn't think so. I assume there is some program running that read the GPS data and sends the info to any ordinary TNC which gets sent out as a regular packet. Therefore, I would think ANY TNC would work OK for APRS.

APRS is all I hear these days. Does ANYBODY still use packet for keyboard to keyboard communication? I'm desperately looking for other ops in Western WI (to do some 2m and 70cm SSB testing with packet) to chat with on good old packet.

All,

I'm an Advanced studying for my Extra, and so far I am getting 66% on the practice exams without even studying after about 3 years of homebrewing. I need a few extra points to make it over the top, and since I am a builder (of sorts) I would like to do it using the electrical principles part of the exam.

However, the questions pool provides the answers but not how to get them. I'd rather be able to understand how to arrive at it without a calculator.

Problem class 1: impedance and phase angle of RLC parallel circuit where component values and frequency are known.

Problem class 2: impedance and phase angle of RLC series circuit where

component values and frequency are known.

Could I calculate these graphically using tip-to-tail summation of impedance vectors?

>From what I understand, |Z| = 2 pi F L, |Z| = 2 pi / (F C), |Z| = R
But how can I get the phase angle or the conjugate pair so that I can do the vector addition?

Thanks in advance,

The Eternal Squire

I was going to ask what study materials you're using -- but you're not, are you?

IIRC this is discussed in the ARRL handbook, which you should have if you're homebrewing.

You calculate the series circuit impedance by adding the impedances of the parts, which you can do graphically, or by adding all of the real parts and all of the imaginary parts. You must calculate the parallel circuit impedance as 1/(the circuit admittance), the latter being the sum of the admittances of all the parts.

Set up axes with R being the horizontal axis and X the vertical axis. To enter a value of R of, say, three ohms, begin at the origin and draw a vector that points to the right, 3 units long. To add a reactance to that, draw a vector from the tip of the R vector, but going up or down -- inductive reactance goes up, capacitive reactance down, with length equal to the amount of reactance. [XL = 2 * pi * f * L, XC = 1/(2 * pi * f * C)] You can add any number of Rs and Xs this way. When you're done, draw a vector from the origin to the tip of the last vector. Its length is the magnitude of the total impedance and the angle it makes with the real (R) axis is the phase angle. In terms of R and X, the horizontal distance from the origin to the tip of the last vector is the resistance of the total impedance, and the vertical distance is the X.

What you've been doing is adding impedances in series, so that's appropriate for figuring the total impedance of a series RLC circuit. To work with parallel circuits, do the same thing but with conductance and susceptance rather than resistance and reactance. The horizontal axis is conductance (1/R) and the vertical axis is susceptance (1/X). Vectors representing conductance point to the right; inductive susceptance points down and capacitive susceptance points up. When you get finished, the distance from the origin to the tip of the last vector is the magnitude of the admittance (1/|Z|) and the angle from the real axis is the angle of the admittance. This is the negative of the angle of the impedance.

This is hard to explain without diagrams, but I'm sure there are lots of good graphical explanations available in handbooks and on the web.

You need some DEFINITIONS made clear first. See following...

>Problem class 1: impedance and phase angle of RLC parallel circuit
>where component values and frequency are known.
>
>Problem class 2: impedance and phase angle of RLC series circuit where
>component values and frequency are known.
>
>Could I calculate these graphically using tip-to-tail summation of
>impedance vectors?

...if you have some polar-coordinate graph paper, yes.

>From what I understand, |Z| = 2 pi F L, |Z| = 2 pi / (F C), |Z| = R

WRONG. Impedance Z = Resistance R + j Reactance X for a series-
resonant circuit. Further, X_L = 2 pi F L and X_C = -1 / (2pi F C).

"|Z|" is MAGNITUDE of impedance; you can't do "phase calculations"
using just magnitudes of either Z or Y.

Note: Admittance Y is composed of conductance G = 1 / R (real
part) and susceptances B_L = -1 / (2 pi F L) and B_C = 2 pi F C
(imaginary part).

>But how can I get the phase angle or the conjugate pair so that I can
>do the vector addition?

A "conjugate match" (or "pair") results when the magnitude of
inductive reactance is exactly equal to the magnitude of capacitive
reactance. Their relative phase angles are 180 degrees and
opposed; they "cancel" each other. In a series-resonant circuit
that leaves you with ONLY the RESISTIVE part of the complex

number expression for impedance.

|Z| = SQRT (R^2 + X^2), Impedance phase PHA = Tan (X / R)

You must assign a polarity to X in order to maintain relative phase angles. Capacitive reactance is assigned a negative value while inductive reactance is assigned a positive value.

For admittance Y (such as with a parallel-resonant circuit), the magnitude (|Y|) is the same square-root of the sums of the squares (and thus always positive), but the inductive susceptance is negative and the capacitive susceptance is positive in value.

Doing "vector plotting" is generally NOT a good short-cut way to get acquainted with either Y or Z...UNLESS you ALWAYS keep in mind the relative phase of inductance and the relative phase of capacitance...and forget the small frequency differences where reactance/susceptance of L is bigger/smaller than reactance/susceptance of C. AT RESONANCE the angles are EQUAL in magnitude but opposed in phase; they equate to zero.

The rules of arithmetic of the "rectangular form" of complex quantities is well-known and mentioned in all sorts of texts, including the mathematics handbooks. Going through numbers with rectangular form is no more harder/easier than trying to plot vectors with polar form representation.

Assignment to the student: Learn the rectangular-form arithmentic rules for complex quantities. ANY text that has anything to say about complex quantities will have those rules.

A hint to keep from re-inventing the wheel. The HP 32S and 33 scientific pocket calculators have both forms' arithmentic rules preprogrammed...AND they do both the real and imaginary part calculations and answer displays like right now. The HP 33 costs about $50 new.

If the angle of the admittance is 20 degrees, the angle of the impedance is -20 degrees. Draw a set of axes. Draw a vector at an angle of 20 degrees from the real (horizontal) axis (20 degrees counterclockwise from the axis). Now draw another vector at an angle of -20 degrees from that axis (20 degrees clockwise from the axis). Are they in opposite quadrants?

Source record: 17346

THANKS for explaining it so simply.

>From the Advanced part I already knew:
1) P = I I R, P = EI
2) ELI the ICE man
These came in handy since the Extra restates some Advanced questions.

I've taken the EHAM practice tests for extra and passed them 3 times in a row by memorizing:

1) Tip to tail reactances for magniture and angle for series resonant circuit
2) Tip to tail reciprocal reactances parallel resonant circuit, take reciprocal back and opposite angle for answer.
2) BW = F/Q (sorry for the mnemonic: f**k over you, you rhymes with Q)
3) reactance = 2 pi F value, reciprocal for capacitors

And now I am getting 77% to 85%, which is enough, I think. There's sections of the exam which are not relevant to my use of the hobby, just as there are other sections not relevant to other people's use.

I am beginning to understand that what the Extra written test is purported to measure is exposure to a number of facets of amateur radio actively pursued over a number of years. Essentially, if you practice at least 3 to 5 seperate parts of amateur radio for at least a few years, you'll already know the bulk of the exam.

That's what got me 55% - 66% of the way already. All I needed to do was practice a little to extend what I already knew about circuits from building.

I'll keep practicing till VEC time.

Thanks a million, folks!

>
> The Eternal Squire

Two problems.

1. It's XL / R. There's no such thing as XR, in this context anyway.
2. Q = XL / R only when the R and L are in series. The Q of a parallel R-L is R / XL.

You can remember those by using a little thought. The Q of an inductor is highest if it has zero series resistance or if it has infinite shunt resistance. Conversely, if you put a very large resistor in series with an inductor, you won't be able to distinguish the circuit from just the resistor. So the Q will be very low. In the parallel case, a low value of resistor will make the inductor become insignificant, trashing the Q.

Good luck with your exam!

Message-ID: <1125494300.955139@athnrd02>
Source record: 17402

Hi,

I wonder if I could tap into some collective insight here while waiting
for a manual and schem, (thanx Joe), here's where I'm at with the radio...

1. The machine comes on, I get a display, all leds for frequency bands
are on, Iguess that only FM, default, or the last band selected should
be on) half of them dimmer than the other half. Can repeatedly turn
radio off and on if no other function/button is selected. If I push a
button of two, I can neither turn the machine off, nor select any other
bands, have to unplug...

2. When the machine sits a bit, off (power plug attached) It comes on,
and now I am even able to tune a bit w/ the encoder, and even key in a
frequency, and it changes, and plays a bit, then dies...Letting it sit a
couple of minutes, it can be switched back on, and tunes and plays a bit
more, starts to growl...and then the sound stops, its stuck and I turn
it off..

While I'm not even a mediocre tech, it sounds like a cap is initially
empty, charges, then starts to leak...IIRC, a power supply cap, or drop
in ps voltage might be might explain the growl.....
Maybe the same in the 5v supply? Or should I freeze spray the thing???

The radio uses, AFAIS, among others,

M5840 cpu
MM5481 led driver?
MM5368 oscillator
TDA1571 mixer
TDA5700 radio chip

Anyway, would really appreciate some help....

regards,

nikos

Hi Frank,

I've done something just as easy - I unscrewed the LO input to the first mixer but left it close enough to couple in some LO. Problem fixed, but gain - of course - well down. Then I reinstated the first mixer LO and did the same thing with the third mixer LO - with the same result. If my brain is working this means that AN, if not THE, overload is occurring beyond the third mixer. I still thing the first mixer may be the area to work on, though. Any thoughts?

KBO, as Churchill used to say!

Thanks,

John

From: John A <e45gkf@nosp.am.yahoo.co.uk>
Message-ID: <df6mmf$858$1@newsm1.svr.pol.co.uk>
Source record: 17404

I've an HP 8558B Spectrum Analyser with dud diodes in its first mixer (one shows 0.33v forward, high resistance reverse, the other 11 ohms either way around)

The official part 08558-20095 and its replacement 08558-60152 have long become obsolete. Can anyone suggest a substitute? The application is in a low power balanced mixer mixing input signals in the range 0 to 1500MHz with a Local Oscillator tuning from 2050MHz to 3550MHz to produce a signal passing through a 5000MHz low-pass filter to a 2050MHz bandpass filter. The present diodes are small glass wire-ended diodes about 4mm long and about 1mm diameter.

Many thanks in advance.

John

Can you replace the mixer with something from Mini-circuits?

Hello John,

I have a UHF mixer in my junkbox. It has a pair of of glass
Schottky diodes about the same size as yours. I think they
are HP 8000 series. I know that they work well on 23CM.
Picture here: http://homepage.eircom.net/~ei9gq/diode.jpg

They are yours if you want them.

4074. What Is Ham Radio?.....A Weekly F.A.Q.

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-09-01 18:11:38 UTC
From: Polymath <aiyr.r.bean@lycos.co.uk>
Message-ID: <1125598298.766344.4330@g14g2000cwa.googlegroups.com>
Source record: 17407
Cross-posted to: rec.radio.amateur.policy,uk.radio.amateur,rec.radio.amateur.homebrew

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

Hi. I'm repairing a H.P. 6111A D.C. power supply and need to replace a shorted diode. It is CR32. If anyone out there has the service manual, could you please tell me what this part is? It seems to be marked GE1-3.2Z so it's not a stretch to think that it's a 3.2V zener, but I'd like to know for sure. Thanks.

Ham Radio (sic) is full of myths.

Do not be taken in by them, no matter how badly expressed.

The following is a collection of items that have been claimed as facts by supporters of UK 'ham radio' (sic), that needed correcting in order not to mislead the uncritical reader

Bookmark for future reference, as these items tend to recur.

New items added. This is Version V. It replaces all other Versions.

[ ] In the UK, no repeat no licence of any kind is necessary to specify, design, construct, modify, repair, own, or (under some circumstances) test an Amateur transmitter.

[ ] A pass in a current examination for a UK Amateur Licence qualifies the successful candidate for the issue of a UK Licence. Holders of the appropriate levels of licence are permitted to operate transmitting equipment that is not subject to a formal approvals procedure, and to carry out technical investigations. A qualification for a Licence, or the Licence itself, is not, repeat not, a qualification to specify, design, construct, modify, repair, or own transmitting equipment. See above.

[ ] Before sunrise on Friday, September 1st, 1939, Germany attacked Poland at 4:45am, when the Battleship "Schleswig-Holstein", on a so-called goodwill visit, opened fire on the Polish naval depot and garrison at Westeplatte. World War II had begun. An hour later, first German units crossed the Polish border. Britain entered the war two days later. She did not repeat not start WWII.

[ ] Because the 'dimensions' of both sides of the Radar Range Equation need a term having the units of square metres in order to balance, references to ratios of these terms expressed in terms of decibels does not repeat not imply that they are in themselves a ratio of powers.

[ ] FM can be demodulated by an AM receiver using the 'Slope Detection' method. Placing an NBFM signal entirely within a channel in a channelised AM receiver is not repeat not Slope Detection.

[ ] A company's Returns Policy is not repeat not an admission that it deliberately produces shoddy goods, no matter how well wrapped at the time of purchase.

[ ] An IP Address in the headers of one's posts is not repeat not Secret Information.

[ ] An exemplary driver is not repeat not one who makes an obscene gesture to show that the other driver is an idiot.

[ ] An exemplary driver is not repeat not one who repeats an obscene gesture to confirm that the other driver is an idiot.

[ ] XRC is not repeat not a suitable method of differentiating between the 80 percent of metals that have FCC crystal structure.

[ ] Millimetre-waves are not repeat not generated by 'nuclear emissions'.

[ ] The length of the day on this planet is not repeat not 23H20.

[ ] A spring/damper model is not repeat not a mechanical analogue of a capacitor/inductor.

[ ] Dehumidifiers do not repeat not work by absorbing heat.

[ ] Gas Company piping is not repeat not blue in colour.

[ ] 1 deciBel is not repeat not equal to 10 Bels.

The differance is the material the copper is on. It can cause the tuned
circuits to be differant and it may be so lossey the material will burn if
the power is high enough.

It could be the dielectric substrate material of the board as Ralph
wrote, or it could also be just how the board is laid out. At least,
it's not quite clear to me from your question that it's strictly the
board material.

As for material, for low-power things at least, we generally don't
bother with expensive Duroid or Teflon or similar substrates out to
1GHz. We find that good FR-4 fiberglass-epoxy material will usually
work OK. One of the concerns that you should be aware of, though, is
that the dielectric constant of FR-4 is NOT as well controlled as the
dielectric constant of the better (and much more expensive) RF
substrates. Also, the dielectric constant for FR-4 is quite a bit
higher, leading to narrower traces and therefore higher loss, to
achieve the same transmission line impedances (or smaller pads to get
the same capacitance). So if you have a layout designed for some
particular dielectric constant and it uses transmission lines and/or
physical structures to do filtering or impedance matching, expect to
have to modify it to work properly if you use a different substrate
material. Obviously, it's also important to pay attention to the
dielectric thickness if you're trying to get particular microstrip
impedances.

The freeware "RFSim99" program has a tool for doing some simple
microstrip calcs, and you should be able to find web applets that cover
much more complicated cases like buried microstrip, stripline, balanced
microstrip, etc. You can also find free/student/trial programs that
analyze more complex structures, though all that may be going well
beyond what you're interested in.

Cheers,
Tom

I have SSB Electronics transverter LT2S. Its 116 MHz crystal oscillator is about 500 Hz off the frequency eg. running somewhere 116 000, 500 kHz. How could this be tuned to pulled 116 MHz? Or is even impossible/too hard to do?

See picture http://www.g1ogy.com/projects/LT2S/page13.jpg

The oscillator is T1/Q1 I am talking about. Any ideas, any help?

I haven't touched it. But as far as I understand its there to avoid
oscillation
to disturb regulation process insuide L09. So it should have nothing
to do with the crystal "pushing". (Let me know if I am totally wrong... :)

4091. Old Fashioned SS QRP CW TX ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-09-03 13:57:48 UTC
From: SpamHog <n1jpr@hotmail.com>
Message-ID: <1125755868.846171.213790@g47g2000cwa.googlegroups.com>
Source record: 17424

I'd like to build myself a small SS QRP CW TX with a broad transmit frequency range (say 3-10 or 5-15 MHz), and clean output. Something I could use now on the current ham bands with a CW-capable digital portable RX, but could forget in a cupboard and use anywhere else if the need / right arises in n year's time.

Hardwired band limits may look reassuring from a legal standpoint, yet almost all commercial radios DO let you get into trouble, frequency wise, so what the heck... + you don't know what the future has in store.

I figure it would be plenty to put together the following:

- always on VFO

- a couple of quasi-linear _tuned_ (!) amp stages
built around a 3-section variable capacitor

- no bandswitching, no plug in tuning coils
or HRO-style coil drawers

- always-on buffer

- power keying on PA

- electronic QSK

- switched receive-mode VFO-offset cap,
patched it into QSK,
to kick it way off the operating frequency
(and off the _amp_chain_passband_ as well !)
& fully kill output + avoid any issues
in isofrequency operation

- pi network, PA current meter.

I'd draw the line this side of DDS, with huff-puff to be perhaps added at a later stage, but I'm open to convincing.

I could sure dream up a circuit, but I wonder where to look for inspiration. I know e.g. no solid state professional transmitters of such ilk...

1960's solid state tactical radios perhaps?

Ideas anyone?

Pasi-

The 1 microfarad capacitor prevents the regulator from oscillating.

L7 would normally be adjusted for maximum output from the oscillator stage, but may also have an effect on frequency. Since it is all you have to adjust, I suggest you adjust it.

I believe the crystal is connected in a series-resonant configuration, which is less affected by circuit values. The only recourse may be to purchase a new crystal.

==========
If crystal is indeed in series-resonant config. , by putting a trimmer of a
few pF in series with the crystal, it will highly likely be possible to pull
the freq 500 Hz.
After all this is only just over 4ppm of the nominal frequency.

Experimental Methods in RF Design, available from the ARRL. Or its predecessor _Solid State Design for the Radio Amateur_. The latter book is out of print, but you might be able to find a used copy.

It looks like a fairly low inductance which resonates with
the 12pf, 68pf and other capacitances in the oscillator to form
a 116MHz tuned circuit. Try adjusting it to see if it will
pull the oscillator to the correct frequency. If you turn
it too far, it will reduce the L.O. output or stop it
from running. If you are not happy with the result, you
can always put it back where it was.

If all else fails, you could try putting a variable capacitor
or inductor in series with the crystal.

Ed,

What is the best way to know the value before i touch it?
Should I measure the voltage after this coil - or how?
And most probably there is RF-voltmeter needed?

Count the number of turns as you adjust. If it has little or no effect
on frequency, return the slug to its original position by turning in the
opposite direction for the same number of turns you counted while
adjusting it.

It would be very difficult if not impossible to find the
exact inductance of L7 while it is in circuit.

Just count the number of degrees of rotation you make
to the tuning slug. You could mark the slug and former
with white paint or tipex before you start. If you don't have a
VHF frequency counter, you could use a 2M beacon as a frequency reference.
Most of the 2M beacons audible from here are correct to within +/- 200Hz.
GB3MCB is usually within 100Hz.

Even a very good crystal oscillator is unlikely to
be stable to less than 1 ppm, so there is little
point in trying to get an error of less than 100Hz.

Hi everyone,

Transverter is now on correct frequency. LO was tunable through
this L7. And it is still oscillating after the pull :)

I was very pessimistic that this L7 would affect on freq. Thank you
for your advice. Btw, I have to say that this German piece of electronic
has really good quolity inside the box.

Hello,

Try to get hold of an HW8, an old Heathkit QRP CW Transceiver.

Lots of modifications and/or extensions can be found on the internet.

Use an old RC4 (Drake) for listening. With some effort, you can let those
two rigs transceive.

Plenty of projects around that idea!

Have fun.

I was poring over a HW-9 schematic already.

Very cool, cept it's anything but broad range: doubler/tripler, mixers, LOs, all sorts of acrobatics that cut down the number of components but make the whole more inflexible.

Right now I am thinking about using:

- a signal generator

- 1 driver and 2 or 3 massively derated finals in parallel, all AB class or so, with broadband RF transformers, i/o at 50 ohm or so

- perhaps a bit of negative feedback

- putting all the filtering at the end, such as 3 tank circuits with 3-section VC + pi network; doing so would possibly simplify the mechanics of providing effective shielding.

Hi Fero,

Since I'm not familiar with the nRF905, I can't really anticipate what problems you might run into. I do expect that at 900MHz, if you can come up with a proper layout and execute it correctly, standard FR-4 (modern fiberglass-epoxy) dielectric shouldn't be a significant problem. I'm assuming that the whole board is small and you don't have more than a couple cm trace length. Obviously, if you ran a few meters of microstrip, you'd have noticable loss. Perhaps someone with some nRF905 experience can give you more help. I did bring up the Nordic website, but the ap note files for the demo boards were in some format my 'puter doesn't understand. (Why doesn't eveyone include a PDF version??) Since Nordic seems to try to provide lots of info on their web site, perhaps they would answer an email about your concerns.

Cheers,
Tom

4105. Re: Stable Regen Receiver--Does it Exist??

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-09-05 18:01:29 UTC
From: SpamHog <n1jpr@hotmail.com>

Source record: 17438

I assume you are talking about temperature induced drift, as opposed as frequency lability due to hand effect, changes in regen setting etc.

I have experienced such stability over time that SSB pitch would stay dead on for days (run on and off) in the shortwave range with the radio tuned on a volmet station half a continent away. In this instance, I was running a 1-tuber with direct heated filament, battery powered, and cap-throttle regen control, but the lessons apply in general.

The main tricks in my book are quite simple:
- keep oscillator power as close to zero as humanly possible
- keep voltages stable
- select LARGE components and hookup wires
- ensure ventilation!

In a word, make sure the oscillator basically runs at ambient temperature.

If you were referring to frequency lability caused by other factors, I have good news in the hand effect department, and mixed news in the regen control area.

Hand effect can be more or less got rid of by proper shielding or decoupling. You can find an interesting discussion here: http://tinyurl.com/dr936 .

In a word: keep your body away from ANY capacitance related to the oscillating tank circuit - and that mainly refers to the ANTENNA, not the variable capacitor or the coil. If there is a sizeable antenna-case capacitance, then a change in body-case capacitance affects antenna and inevitably the tank circuit too.

So the oscillating tank circuit must be properly decoupled (usually by RF amp/buffer stage ahead of the regen detector)
OR
it must be well enclosed + the antenna coax fed
... or both.

I would like to experiment with cap-decoupling by putting a slitted-shield around the tuning coil, and putting a separate antenna coil next to it, but never got around to doing so. Even theoretically, the idea of such a trick gives me a headache.

In the regen control department, the mixed news is that capacitive throttling is considered the "best performing" way to go, but can't avoid to affect the tuned frequency.

[In theory you could, of course, what with a small co-shafted VC that removes capacitance from the main LC as the throttle cap adds it, but it must be a pretty complicated law, and I don't know of anyone who tried it :)]

You can instead turn to the gain-control way, DC-controlling one of the following:
- second grid voltage in a pentode
- plate voltage in a triode
- base voltage in a transistor
or some such like.

All of the above minimize frequency change especially in tube designs (where varicap effects are basically nonexistent), but can suffer from annoying hysteresis, in my experience more than cap throttle. Not sure where the "high performance" advantage of cap throttle is though...

Another trick I wish I had tried is changing a *stabilized* voltage, as opposed to using a simple throttle pot. That could be done with a variable regulator IC and might remediate the hysteresis.

Another trick is to use a couple of effects working in opposite directions, such as a resistive throttle that adds gain but shunts more RF to ground, such as in the Charles Kitchin "Beginner's Radio".

See www2.arrl.org/tis/info/HTML/regen/
with many derivatives linked in this article of mine:
http://www.geocities.com/filippo_cattaneo/desert-ratt.html .

I think the same trick may be in use in the MFJ-8100 regen, but I can't tell what's trimmer and what's main control pot.
(hand drawn schematic may be here:
www.diagram.com.ua/list/mogik.shtml
sorry Martin!).

So, there's hope.

The application note for the NRF905 does specify FR4 board with 1.54mm substrate thickness. FR4 is the board material used for almost all printed circuit boards, so you can use a regular board and just make sure the thickness is 1.544mm.

http://www.nordicsemi.no/files/Product/applications/nAN900-04_nRF905_RF_and_antenna_layout_rev2_0.pdf

here is the link for most od the documents related to the NRF905.

I have no idea in what the HW-9 differs from the HW-8 in the transmitter
stages.

I know the receiver of the HW-9 is more elaborate than the direct reception
of the HW-8.

I do not feel comfortable with broadband signal generators in transmitters
since they tend to be noisy and jittery.

To some extend, it could work on FM, but I doubt the results will be worth
anything in SSB.

Signal generators produce also lots of spurious; filtering at the end stage
will be a real challenge.

I still have the intention to use the "inj." output of a Drake R4B, mixed
with the output of an x-tal oscillator (somewhere around 6 MHz, I don't
remember exactly) to send on the frequency the R4B listens on.

With some fiddling, you could find in every receiver a frequency to mix with
a fixed oscillator to get the same effect.

The resulting signal will need filtering before any amplification, so much
for your wish to go broadband!

On the other hand, filtering over a broad band at the end stage is OK only if you intend to use a dummy load at all times (HI). A real antenna will not present the required impedance over the entire frequency range to the output of your filter. The garbage you intended to filter will only be partially taken care of.

So you see, quite a challenge!

Fun, isn't it ?:-)

I actually made a hybrid 300MHz IF strip that looked a lot like your
lash-up, with soldered-on barriers between sections. Except with
notches for the screened interconnect feed-throughs.

Hello all,

I'm restoring a 50s vintage EICO 720 transmitter. I'm in need of a 50 k potentiometer rated at 4 watts (or above) that is NOT wirewound.

The old part looks like a thin ribbon-like piece of resisitive material bent into a circle and placed inside the pot case. The spring loaded center contact appears to be in good shape, but the ribbon is fractured (microscopically) in two locations along its length.

I have been unable to find a replacement for this part at any of the large parts supply houses.

Does anyone know of a source?

Regards,
Peter Barbella

Is there any hint of who the original maker might have been?

What's the overall diameter of the pot?

Points taken! Never really looked at quality in a signal generator. U
never stop to learn. Signal level garbage in -> AMPLIFIED garbage
out.

A clean VFO or DDS + a tank circuit ahead of the PA looks like a much
better idea.

I have looked at a number of broadband amp designs, and it seems that
they share a real concern with cleanliness:
- linear amplification
- negative feedback (some even DC coupled)
- sometimes push-pull with matched devices.

As far as antenna matching is concerned, I'd first align the cascaded
tank circuits into a dummy load, and never operate without a tuner.

All this considered it looks like broadbanding requires choices that
together lead to a low power efficiency.

Now, re. filtering output with cascaded LC tank circuits, I have a
question stemming from this being the toroid era.

In the old days, multiple capacitor-tuned LC circuits in series could
be aligned over broad tuning ranges by means of slug adjusted coils and
small capacitive trimmers. It was a bit of an art, but satisfactory
alignment was possible.

But you can't easily trim a toroid.

When handling say up to 5 watts RF, do I already have to fear
saturation in IF-type, ferrite-tunable canned coils?

Or, does anyone ever put a small L of that kind as an indictive trimmer
in series with a toroid?

I would try "Electronic Surplus" in Cleveland -- their number is (216)
441-8500

fwiw -- the manual is available on the BAMA mirror
site --ftp://bama.edebris.com/bama/eico/720/720.djvu
you need DJVU to view the manual -- but it is easy to find on the web.

I have an Eico 720 and I'm 99% sure that the drive level pot is wirewound in mine.

It's just part of a DC divider that sets the screen voltage on the 6AQ5 driver/multiplier. There's no AC so wirewound should be fine.

Lotsa radios in the 50's/60's and QST construction articles show drivers with wirewound pots on the DC screen divider.

It has to dissipate a good chunk of heat. The way that Eico built this radio there are all sorts of resistors to drop from the HV to B+ for the oscillator/driver, it gets real toasty due to all those dropping resistors.

Last time I looked 50K 5 or 10W pots were available in wirewound, I think Allied or Mouser had the Ohmite units. I don't think you'll find this sort of dissipation available in a ceramic pot. I'd recommend that you go for something more than 4W if you replace it because it does get warm.

Tim.

I know that mine, like Tim's was wirewound, and I can remember hassling with a replacement. The wire was very fine and susceptible to breaking.

These days, if I wasn't too concerned with keeping it exactly as EICO designed it, I'd probably use a power mosfet with a small heatsink, as a source-follower driven by a lower-power higher-resistance pot. I'd include a zener from gate to source, and maybe a 10 meg resistor from gate to source (in case the pot wiper opened) and maybe a 1 meg resistor from pot wiper to gate (to limit max pot wiper current). That would provide a fairly "hard" voltage output at the FET source, which could be "softened" by adding a resistor in series. It may be useful to drop something like 220k ohms/1W to ground from the output, if there isn't already a resistive load to ground in the circuit. The parts would likely be easier to find than an appropriate direct-replacement pot, though maybe not.

Cheers,
Tom

Unless you want to restore this valve equipment as much as possible to its original state ,you could of course adjust the screen voltage with a carbon track potmeter , using a high voltage transistor ,a high voltage zener diode and a few more passive components.

Had a Yaesu FT-470R 2m ssb/fm transceiver in recently for repair - VCO was faulty. The module had been encapsulated in expoxy resin, and took AGES to chip out with a fine wood chisel (and lots of swearing). Broke a few components doing it, but could replace them so did. Pig of a job.

I consider this to be the definitive reason why beeswax is a better potting material for VCO's.

What more do you want? - its cheap, readily available, easy to use, recyclable, easy to get out for equipment maintenance, smells ok when melted (better than modern chemicals) - need I say more?

Hi Tom,

I have got one more question : could this RF-4 material be used for
frequency up to 2,4 GHz too ? (blue toot)
Namely, Nordic offers chips for this frequency, too.

Thanks a lot.

Fero

I used ordinary FR-4 for a 6 GHz pulsed oscillator in a commercial product, and the last I heard it was working fine in mass production. But it's used only in a dry environment, and doesn't have any high Q networks or filters. If your design can tolerate relatively high loss and a moderate dielectric constant (about 5) that varies with temperature and humidity, FR-4 is fine. If it can't, you should consider Rogers PTFE board products or something similar.

Roy Lewallen, W7EL

True. This transmitter only has a single HV winding, so all the B+'s for the non-final stage go through big power dropping resistors, and then there's all the screen bias dropping resistors too.

I haven't added it all up, but this transmitter probably dissipates close to 70W when not key-down in dropping resistors just to avoid a second winding on the power transformer. If I were to re-do anything I'd start by adding another power transformer for screen bias and non-final B+'s.

Tim.

> I have repaired a number of Epoxy Potted VCO modules by simply resoldering ALL of the PCB board connections !
The source of the problem is difference in the Coefficient of Expansion between the Epoxy potting compound and the PCB and the solder connections. Close inspection (under a microscope) will show that the joints in question have been fractured by repeated thermal cycling. Hand resoldering, rather than the original Wave-Soldering will produce a much stronger bond between the component leads and the PC board and reduce the problem.

I always have used paraffin -- way more 'solid' and takes more heat
to melt than 'normal' candle wax.
Maybe I was violating some law...
YMMV

It could be. One problem with temperature compensation is that the various components of an oscillator have differing thermal masses, thermal conductivities and hence thermal time constants. So it helps to have everything thermally connected so all component values change at the same rate.
If beeswax conducts heat well, then potting the oscillator with it would assist temperature stability.

The beeswax also stabilizes the components so they don't vibrate for
whatever reason. Vibrations can induce changes in values for susceptible
components resulting in modulation of the output frequency.

Thats a good point, Yukio - BUT..... its usually a major job to get to
the bottom of the vco module anyway - (it was in the 480R I did) - to
just resolder, then re-assemble into the board would have been easier,
but it would also have meant another load of massive thermal stress on
everything if it DIDNT work, or failed again. Thats why I did the
chisel out and replace job.

I did manage to establish (by using a steel probe and poking) it was
one of the epoxy potted on board transistors - I wonder if the two
epoxy mixes were pulling and pushing each other apart?

Interesting speculation - I just fix the things based on 20 years of
stuffing around, burning fingers, and cursing pig ignorant engineers
who design radios without thought of serviceability!

And if you have the right iron (a big one) and can solder well, its not really a problem to do - just tedious, but worth it for a long term fix.

http://www.kayelaby.npl.co.uk/general_physics/2_3/2_3_7.html is also
interesting, especially if you follow the link to the polymers page at
http://www.kayelaby.npl.co.uk/chemistry/3_11/3_11_1.html#3_11_1

It looks as if beeswax and paraffin both have thermal conductivities
of about 0.25 (when measured in W / (m K)), and that epoxy cast
resins are in the range of 0.17 - 0.21.

This is one of several reasons that the best approach in designing an oscillator -- or any other temperature sensitive circuit -- is to use components that each have as small a temperature coefficient as possible. That is, first minimize the inherent drift. Then, if you must, compensate what drift remains.

Gentlemen,

I am attempting to identify the tower manufacture of the tower pictured at: http://www.ppinyot.com/antenna.htm. I would like to properly design a base for it given the manufacturers specs plus perhaps pick up additional sections.

The tower seems to be of a stamped steel design (not tubular) with stamped steel cross members. It has been well maintained by the silent key's son. I gather it is about 10 to 15 years old. There is an unpainted ladder chained to one side for storage. Please do not confuse this as part of the tower.

Also if you happen to recognize the beam please Identify it too.

Unfortunately some one discarded all the paper work not knowing it's value.

Thanks Paul

I need an LF to 30 Khz preselector (passive) for a homebrewed receiver I'm building. I have most of the details worked out, but I am stuck on the preselector design.

I want one band to cover 50 Khz to 500 Khz (or 1 Mhz). The second band would be 1 Mhz to 30 Mhz. 50 ohm input with moderate Q (don't want to have to retune it every 100 Khz. The LF unit can be very high Q, peaking it every few Khz is ok as most of the signals in that range are narrowband signals anyway. Input impedance is standard 50 ohms.

I'd REALLY like to have one assembly do the entire job, but it appears to be a tall order as that's quite a wide range to cover with one tuned circuit.

Google returns to many hits even if I narrow down the search parameters, I tried google.

It appears I need to use some sort of permeability tuned variable inductor in conjunction with a variable cap. Have no idea how to go about this or where to buy permeability tuned inductors.

Any suggestions?

T

That would be 1:10 (or 1:20) frequency range.

>The second band would be 1 Mhz to 30 Mhz.

That would be 1:30 frequency range and would require a 1:900 reactance range, if only one element (inductance or capacitance) is tuned, which would be completely unrealistic. The alternative would be to tune both the inductance _and_ capacitance in the 1:30 range. However, with a 300 pF variable capacitor, the minimum capacitor would be 10 pF _including_ all stray capacitances, not very realistic. I have no idea what a realistic tuning range would be for a permeability tuned inductor. I have only seen those in FM receivers (87..108 MHz), which only about 20 % tuning range.

>50 ohm input with moderate Q (don't want to
>have to retune it every 100 Khz. The LF unit can be very high Q,
>peaking it every few Khz is ok as most of the signals in that range
>are narrowband signals anyway. Input impedance is standard 50 ohms.

Maintaining the constant impedance if both inductance and capacitance is tuned would be a challenge.

While maintaining the power match makes some sense in HF receivers (and also if you are using some small magnetic loops on LF/MF), but otherwise, I would question the idea to maintain the 50 ohm resistive input impedance on LF (and possibly also MF).

On LF, any practical random wire antenna would have a high capacitive reactance. On LF I have simply used a parallel tuned circuit and connected the antenna to the hot end of the circuit with a small (10-100 pF) capacitor. Of course, the tuning scale will not be accurate if you change the antenna, since the antenna stray capacitances will detune the resonant circuit. Use a secondary winding or a source/emitter follower to get the impedance down to feed a 50 ohm receiver input or feed a coaxial cable (if the preselector is just under the antenna).

If you intend to use magnetic loop antennas on LF/MF, which have a low efficiency, I would suggest using a (remotely)tunable loop as the preselector, with possibly a preamplifier at the antenna.

I would strongly suggest splitting the HF bands and switching in various inductors for various bands and use an ordinary variable capacitor.

The situation is quite problematic on LF, since you would need a variable capacitor with a tuning range int several nF to keep the resonant circuit impedances at manageable levels (otherwise, it would be quite "touchy" due to stray capacitances). With practical variable capacitors, you would have to add parallel padding capacitors, with would further reduce the tuning range.

Permeability tuning might be an option. You could try making a coil and slide a ferrite bar (from a medium wave antenna) into it, however, I have no experience with this.

I realise that you are after a passive solution but I wonder if an
op-amp or two in a Q multiplier configuration *for the first band) might
be a better idea? You could then tune the feedback/gain of the device
with a R/C combination rather than large values of L. You could of
course set the gain to 1 if you wanted.

Just an idle thought.

Cheers Bob W5/VK2YQA

Thanks Paul,

My old Drake C line had a multiple ganged permeability tuned inductor mechanically coupled to a variable cap.

One of the assemblies tuned the front end, one peaked the driver stage, etc.

It covered from 1 Mhz to 30 Mhz with a half turn on the front panel preselector control. Most likely the variable C and L tuned together maintained a desirable Q across all the bands.

I was hoping for something similar, but have no idea where to get permeability tuned inductors today.

Regards,

T

Paul:

It looks a lot like the one I have (except mine is still in the standard galvanized steel, not painted red).
Mine is a Rohn HBX, though what is there could be a BX, depending upon the sections used at the top.
It was generally available up to 64' in the BX version, and 56' in the HBX version. The big difference is the top section is smaller on the BX version. Each section is 8 feet tall, and the standard footing

http://www.antennasystems.com/towers.html#BXTOWER

has some information about the tower. I have a printed copy of the manual somewhere, but it would take months to find it, as I'm in the process of building a new QTH.. I had also found a copy on the internet somewhere, but it was lost during a hard disk crash, but I imagine you could search for the manual given the model number.

The base in the pictures is a tilt-over mount for the tower. I used the standard (non tilting) mount, and it served me well with a large Cushcraft X-9 beam on it, plus a 2 meter 11 element beam above that, and several wire antennas off in odd directions. It will be going back up at the new QTH. It is the 48 foot HBX version.

Because it is in 8 foot sections, you can take it down or put it up a section at a time, but having done that, I find that it's much much easier, faster and safer to just have a boom truck come out, attach a sling to the top, then disconnect at the bottom and let the boom truck operator just lay it down. Works like a champ, is quick and easy. Needless to say, it's going back up using a boom truck, as I'm not into climbing a tower a dozen times a day any more. Once is quite enough, thank you. I can get the tower up and beam on it with a single climb (sling on top of the tower, boom truck lift into place, climb tower, disconnect sling, boom truck operator connects hook to the antenna, brings it up to me, and I bolt it in place). Connect the coax already in place before the tower went up and viola!, tower up with beam in about an hour. Lots of prep beforehand, but all on the ground where I can take breaks and enjoy a beer or two during assembly.

Good Luck, Be safe!

Just about all the radios I've seen with mechanical pushbuttons for station presets used permeability tuned inductors -- the pushbuttons each just positioned a ferrite core to a preset depth in a coil. It wouldn't be difficult to construct one, unless you're mechanically declined like I am.

I thought it was the norm for car radios to be permeability tuned, right
up to the time synthesizers came along. No manually tuned car radio
that I've looked at had a variable capacitor, with the exception of
a relatively recent one that had a frequency counter for the readout.

Car radios would be the best source of the mechanics, at least for
front end tuning and not oscillator use. Of course, the issue isn't
changing the permeability of a coil, that's easy with a tuning slug,
but making it easy to do that from a front panel control, ie the knob
doesn't move in and out. The pre-synthesized car radios would proved
the mechanism. But you did see the occasional article in the old
days about making up such a mechanism, though those tended to be
for oscillators where there was more fuss because they wanted/hoped
for linear tuning.

Some of the cheap imported car radios used the same plastic cased
variable capacitor with mylar film between the plates that were used in
a six transistor pocket radio. They didn't have a tuned front end and
amp like the US made car radios. They were ok if you only wanted to
listen to a local station but they were very poor quality radios.

I think I would use a variable capacitor and electronically switch
the inductor for different ranges, like the broadband L-C Based VCO in
the telemetry receivers I worked on. Diodes were used to short segments
of the inductor, at the grounded end and the band segment was controlled
by simple logic. Bias on hard to short a tap to ground, and reverse
bias it to prevent it from clipping the RF when its off. They used
discrete +/- 12 or 15 volt switching , but a decent buffer amp would
work and could be driven by CMOS or TTL compatible logic. If the
receiver has any switched DC signals to show which band its on, you
could make it change bands without touching it. You could even sample
the L.O. with a counter circuit and use the output to control the
tuning. If you want to g to extremes, you could add a microprocessor
with lookup tables to drive a stepper motor that can adjust the variable
capacitor(s) for you as you tune the radio.

I once told one of the Vice president of marketing at United Video
Cablevision that he was mechanically declined and my boss freaked out.
;-) The VP yelled at him and told him to shut up because it was true,
and he was happy that whenever he had to launch a new channel in the
Cincinnati system that everything was set up and ready for him when he
arrived.

Of course, you could make them as individually tuned coils with a
stepper motor or servo per coil.

Thanks to all that commented. Although I don't have an answer, the content of the discussion was helpful.

I'm not exactly fond of electronic switching, but it's probably adequate since atmospheric noise dominates in the vlf and lf range anyway.

I'm trying to understand the butterworth filter now, with the hope of designing a bandpass filter over a wide range of frequencies rather than a variable unit.

Regards,

T

4164. Butterworth bandpass filter question

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-09-11 16:09:16 UTC
From: TRABEM <>
Message-ID: <euj8i1po8dsokkeedfc4ofouqtsh97mihe@4ax.com>
Source record: 17297

I am trying to scale an existing front end receiver (butterworth bandpass) filter to a different frequency range. Unfortunately, it has a transformer in the original design, so I'm stuck. I also don't know how to handle the load presented by the active front end component other than it's probably not significantly reactive.

The existing filter is for a 7 Mhz receiver, I'd like to have a similar filter design for 50 to 200 Khz.

The filter components and transformer winding details are in the document at:

http://www.amqrp.org/kits/softrock40/SoftRock40%20Assy%20v1.pdf

The input chip is an FST3126, spec sheet is at:

http://www.fairchildsemi.com/ds/FS/FST3126.pdf

The spec for the T30-2 transformer core is at:

http://partsandkits.com/T30-2.htm

I have aade filter design software, but it isn't allowing me to plug in the transformer into the design page of the software....so, I need to know it's equivalent circuit I think.

The transformer winding details are on page 4 of the document and the schematic of the front end is page 9. Ultimately, I need new values for L1, L2, C20, C21 and C22.

If someone can give me a reasonable guess as to the equivalent circuit of the transformer and the IC (U5), I can do the rest of the job myself using the aade filter software.

Thanks,

T

You might try FilDes:
ftp://ftp.lehigh.edu/pub/listserv/qrp-l/tools/fds201.zip

It will let you specify different source and load impedances for the
filter being designed, so you can probably get away without the
transformer altogether. The AADE software has a nicer interface but
I've always liked the functionality in FilDes better.

It looks like the filter is designed for 50 ohms in and out. The transformer inductance is also a part of the filter. It's value should be about the same as L1 so to use it at 50k to 200K, you'll need to rewind for a lot more turns on the primary and both secondaries if you keep the same core material.

Scaling it all and then optimizing for Coil Q of 40 and regular cap and coil values, I get new values like:

L1 680nH -> 100uH
C1 470pF -> .022uF
C21 180pF -> .027uF
L2 1.8uH -> 100uH
C22 470pF -> .022uF
T1 680nH (13:6:6 Turns) -> 100uH (1911:882:882 Turns)

I strongly recommend changing T1 to a much higher mU core material.

This should result in -3dB points at 50 and 200 kHz, flat pass-band and -30dB at 20 and 500 kHz.

Good luck finding a 50 Ohm antenna at these frequncies. An active antenna may be the way to go, otherwise you'll need many acres for all the wire.

==========
If you are happy with the HF receiver as is, would it not be easier and more effective to build an LF (50 - 200 kHz) to HF converter. This should be an easy project and you can select a quiet "HF band" for the conversion.

I have seen designs with a SBL-1 mixer but also a number with the NE612 osc/mixer. Perhaps others frequenting this NG have built such a converter.

OK, thank you very much.

I checked the amidon website, higher mu toroids are available but
looks like they're a little more expensive.

If I want to simulate the filter myself, can I just ignore the series
10 ohm resistors in each side of the transformer secondary? Do the 5
ohm ac series resistance of the switch and the .1 uf capacitor on the
far side of the switch enter into the calculations at all????

I was thinking all those R's and C's get reflected back through the
transformer and should impact the filter values.

If I can ignore the R's and C's on the secondary side of the
transformer, can I simply pretend the primary is a coil with a 50 ohm
shunt (to represent the output impedance)??

When the series 10 ohm resistor, the 5 ohm series ac resistance of the
switch and the .01 cap to ground on the output side of the switch is
factored in, does the output impedance still look like 50 ohms?

>Good luck finding a 50 Ohm antenna at these frequncies. An active antenna may be

>
>

Yep, we can do it. Got 40 acres. But, wasn't planning on using that
many acres:>: My plan was to use a single turn loop, 10 to 15 feet on
each side and step up the impedance with a toroid at the antenna. The
wire is 200 A service entrance insulated aluminum, so it should have a
decent Q if I use some polystyrene caps to resonate it.

Hi,

Hi,

>I am trying to scale an existing front end receiver (butterworth
>bandpass) filter to a different frequency range. Unfortunately, it has
>a transformer in the original design, so I'm stuck. I also don't know
>how to handle the load presented by the active front end component
>other than it's probably not significantly reactive.
>
>The existing filter is for a 7 Mhz receiver, I'd like to have a
>similar filter design for 50 to 200 Khz.

Notice that the primary to secondary (total) turns ratio is
almost 1:1, that both shunt capacitors in the band-pass filter are
of the same value and that the path resistance on either side of
the secondary, through the FST3126M to the low-pass filters is
around 20-ohms. So what you are looking at (to a crude
approximation) is a design impedance of 50-ohm all the way
through.

As for the toroid, for optimum Q you might want to look for a
mix more suitable for the frequency range you quoted (maybe 15?)
and increase the diameter to take the extra wire as you will need
to scale the impedances for use at 50kHz. The FT series, I think,
need less turns for the same inductance and so should be easier to
wind.

Finally, a simple low-pass filter would probably be all you
need here as the transformer primary impedance will be a limit the
low end. Filter response is dependant on source as well as load
impedance and most antennas that you would use at those
frequencies will be quite reactive and difficult to design a fixed
input network for. You may be aware that a lot of HF receivers use
a separate hi-Z antenna terminal for LF/MF.

Having said that, if you do want to use a simple low-pass
configuration, remember that a symmetrical 'Pi' filter with source
and load impedances of 1-ohm and a cut-off of 1-rad/sec would use
two 1-Farad capacitors and a 2-Henry inductor. To scale to new
impedances and frequency, divide C (and multiply L) by the design
impedance and then divide both C and L by the new cut-off
frequency in rads/sec.

Cheers - Joe

Your E-bay ad is very misleading. First of all, the Amphenol logo on
the box is from the '70s, not the '50s.

While it is true that Amphenol no longer makes that connector, its
because they sold that product line to WPI
http://www.wpi-interconnect.com/ several years ago.

Switchcraft http://www.switchcraft.com/ 2501 series is a fully
compatible, and better quality connector line. Then there are still
imported connectors that mate with this old industry standard.

$10 each is an outrageous price. You can find these at a lot of
online surplus dealers and almost any place that deals in older musical
equipment.

BTW, I still have 3 of the 2501F Switchcraft connectors for $3.50
each, and a good supply of the self shorting 2501 MP chassis mount
connector that short circuits the input when you remove the connector
for $2 each. This item is NLA from the OEM. I got a good price from a
surplus dealer who doesn't have any idea what they are, so I bought 25
to replace all of the microphone connectors on my restored antique test
equipment.

http://home.earthlink.net/~mike.terrell/Epcon.html Note: the current
stock on the shorting connector is shown as 3, but I can still get about
1000 additional connectors.

OK, that's about what I thought, but I was estimating closer to 15
ohms for ac resistance between the secondary winding and ground. So, I
was having a hard time believing it could be 50 ohms in and out. It
probably makes little difference though in the filter values or
passband response.

> As for the toroid, for optimum Q you might want to look for a

I was looking at the CT series, specifically a CT-50-57, which is a
little bigger, but probably can contain all the wire easily.

I'm aware of the separate antenna inputs some LF radios have. The
lowfer group has quite a bit of information on antennas, and it seems
that making a 50 ohm antenna or something approaching 50 ohms from a
large single or multiturn loop isn't that difficult.

Making a 15 or 20 ohm antenna is even easier, perhaps I should think
about 15 ohm input impedance and a 15 ohm output impedance since it's
actually easier to handle the antenna step up.

> Having said that, if you do want to use a simple low-pass

Most likely it's probably best to keep it at 50 ohms and not to worry
about the slight mismatch in that frequency range.

Thanks to you and to all who commented, it was just he sort of
information I needed to put me back on track.

What would this solve ? You still need some selectivity in front of
converter.

I would also question the need for a bandpass filter, but a good low
pass filter would definitively required in any case. I would suggest a
low pass filter below 150 kHz in Europe, Africa and Middle-East and
below 500 kHz in the rest of the world to get the very strong LW/MW
broadcast band signals out of the mixer. If 455 kHz IF is used, the
LPF would have to be below 400 kHz in the rest of the world.

>I have seen designs with a SBL-1 mixer

SBL-1 is specified for 1-500 MHz on the RF and LO port, so not really
suitable for this band. However, the SBL-3 goes from 25 kHz to 200
MHz. The SRA-6H goes from 10 kHz to 50 MHz and should be able to
handle up to +10 dBm signals.

>but also a number with the NE612
>osc/mixer.

I have used the Datong LF converter, which uses the Siemens S042
mixer/osc IC similar to the NE602/612 and it definitively needs a
preselector in front of it to get away with spurious responses all
over the LF band from broadcast stations.

Thanks Paul, and yes....you're correct. Building a conventional converter would still require a passband filter, so little is to be gained, except that perhaps someone else has already done the design:>:

Also, this receiver design has no mixer, it is simply a detector and a very linear one to boot. No mixing byproducts are present because there is no non-linear mixer. In effect, this design is already a converter....except that it converts to audio directly from the rf frequency input.

The "spurious responses all over the LF band from broadcast stations" probably don't exist in this type of receiver, which is one of the attractions for VLF use of this technology.

Take a look at the link to the design in the original message and you will learn how it operates without mixers and without non-linear detectors.

It's WHY I so interested in this particular method of reception and WHY I want to make a front end for vlf for it. The concept is explained in a QEX article in greater detail, Im happy to send the url to anyone who wants to learn more about these high performance direct conversion receivers.

Regards and again, Thanks,

T

Actually, the thing you call a detector IS a mixer. You can probably find some references for "H-mode mixer." It's good, to be sure, but it's inaccurate to say that it's _perfectly_ linear. (I'd LOVE to find a practical sampler which had zero distortion...though then I'd need amplifiers with zero distortion, too...)

As someone else pointed out, any practical antenna you have for LF is very unlikely to be a good match to 50 ohms, and is very likely to be quite reactive so that by the time you add components to tune it, the bandwidth will be pretty narrow. So if you have a tuned LF antenna, which is quite usual, the response will be quite narrow, and why would you care about a bandpass filter? I'd recommend a loop with a tuning arrangement at its feedpoint (variable capacitance), and an appropriate preamp to drive a feedline back to the receiver. With that, you won't need any filter, just a transformer going into the mixer (converter-detector-whatever). A while back, I did some work to modify a design you can find at http://www.cpinternet.com/~lyle/bal-pre/bal-pre.htm, so that the control was done as a DC current , which also fed the power to the preamp on the same line that signals come back on. It worked out well. But check out other antenna options from Lyle's website (http://www.cpinternet.com/~lyle/) or others devoted to LF, too.

Cheers,
Tom

Mike, I don't know what kind of a hair you have up your ass, but I strongly suspect the motivation for your post is that you have some off-shore made cheap Amphenol imitations to sell.

You posted:

Your E-bay ad is very misleading. First of all, the Amphenol logo
on
the box is from the '70s, not the '50s.

I simply included a photo of the box so people would realize that these are actual Amphenol connectors rather than some cheap, oriental, knock-off. The fact is that identical Amphenol made high impedance microphone connectors of this manufacture and type have been in continuous use since the late 1940s. My first exposure to them was on Sears "Wire Recorders" circa 1949, and years later Pentron tape recorders during the mid-1950s. Sir, you are obviously too young to remember these days, or too ignorant to recognize truth in advertising when you see it!

"While it is true that Amphenol no longer makes that connector, its because they sold that product line to WPI
http://www.wpi-interconnect.com/ several years ago."

...And who produces a cheap, off-shore manufactured imitation of the original Amphenol's. What was sold to WPI was not the tooling, but use of the brand name only. Sheesh...you really have no clue!

"Switchcraft http://www.switchcraft.com/ 2501 series is a fully compatible, and better quality connector line. Then there are still imported connectors that mate with this old industry standard. "

Switchcraft product were never in the same league with those of Amphenol, and most are/were imported crap.

" $10 each is an outrageous price. You can find these at a lot of online surplus dealers and almost any place that deals in older musical

equipment. "

Read my ad again. The starting bid price is $7.50 inclusing packing and shipping. The $10 price is for Buy It Now, and also includeds free shipping.

"BTW, I still have 3 of the 2501F Switchcraft connectors for $3.50 each, and a good supply of the self shorting 2501 MP chassis mount connector that short circuits the input when you remove the connector for $2 each. This item is NLA from the OEM. I got a good price from a

surplus dealer who doesn't have any idea what they are, so I bought 25 to replace all of the microphone connectors on my restored antique test

equipment."

Good for you. Does that $3.50 price include free packing, shipping, eBay and Paypal fees for youur offshore produced crap, or are you going to shaft your buyers with another $3.00 for packing and shipping?

My connectors are real Amphenols and being sold postpaid. Are yours?

Harry C.

If you read Gerald Youngblood's first QEX article on the SDR-1000 software-defined radio, you will see on page 7 another embodiment of this type of mixer/detector. It was originally popularized and patented by Dan Tayloe, but has recently been reconfigured (for patent purposes as much as anything else I suspect), and renamed 'quadrature sampling detector' (QSD). The original embodiment shown in the QEX article has no transformers.

As a passing comment, one of the writers here said a mixer IS a detector. He's absolutely correct. A detector is just a special case of frequency mixing where the RF is mixed directly down to DC baseband. As another writer said, ALL mixers/detectors, regardless of whether they're the modern switching type or the antique-type based on square-law nonlinearity, have an overload point beyond which they make unacceptable distortion. Switching mixers, which include most double-balanced diode mixer (DBM) modules and most Gilbert-cell IC mixers, just happen to be more linear than many square-law devices up to the overload point, then they go to hell in a handbasket. The QSD is a just special case of switching mixer that can produce quadrature baseband outputs very conveniently, but it is a bit better in the distortion department than many diode DBM's.

Michael, as an afterthought....

I'll immediately send you a Paypal payment for $3.50, if you'll send me one of your "Imitation Amphenol" connectors postpaid (just like I am selling my genuine Amphenols) so that I can examine it and compare the quality of your product with that of Amphenol's (construction, plating, solderability, etc.).

I'll even photograph the two different products side-by-side and email the photo to any newsgroup reader requesting it so they can make up their own minds. Is that fair or not?

Put up or shut-up!

Harry C.

Heresy maybe but I'd be inclined to just dump the transformer and bandpass coils and caps and 10ohms etc. Use opamps for a low pass and a high pass filter. Then add another inverting opamp to provide the antiphase for the mixer chip. High 'Atmospherics' at these low frequencies mean pretty much any opamp will be OK.
Use a resistor to present any input Z to the Ant'.
The FST3126 (or 74HC4066) works well with opamp drive.
regards
john

I'd hardly call it heresy, John. In my search for really good op amps to use up to 50 and 100MHz (very low distortion and low noise), I've come across some that would be really outstanding up to a couple hundred kHz.

In fact, since you can get 24bit ADCs that cover up to that range (e.g., AD7760, AD7762) with very good linearity and low noise, you could make the whole LF receiver with just the tuned antenna, the preamp out at the antenna, _maybe_ a bit of gain, and the ADC feeding into a PC. Then the "quadrature mixing" would all be done digitally, with much better accuracy than you'll get with an analog mixer. Yeah, yeah, you have to write some software to get it to work...but a modern PC should have no trouble keeping up with doing all the signal processing. There may even be sound cards out there with response out to 100kHz--that's an area I don't keep up with.

Cheers,
Tom

Switchcraft is not "Imitation Amphenol" It is an american made
product. I can get you a picture of it if you want. Obviously you have
never used anything from Switchcraft, or you wouldn't question the
quality. It was used in a lot of military and industrial grade
equipment, where I have seen more ham gear with Amphenol connectors.

As far as Paypal goes, I do not have an account. I don't buy or sell
on E-bay, so i really don't need one. The parts i have for sale are the
leftovers where I shut down my business due to failing health. I would
rather sell them cheap than have them end up in a landfill. I used to
sell at a half dozen hamfests every year, but I can't make the long
trips anymore. That leaves the Ocala hamfest that is within my driving
range, and the locals already know how to find me. I did commercial
sound, broadcast and industrial work. I only used Switchcraft, because
of their quality and a reasonable delivery time. At the time they were
a division of Raytheon, who was a large defense contractor.

Here is one online photo of the Switchcraft 2501F connector at Allied
Electronics:
<http://www.alliedelec.com/Search/ProductDetail.asp?SKU=932-1045>

<http://www.google.com/search?num=100&hl=en&lr=lang_en&ie=ISO-8859-1&newwindow=1&q=switchc
raft+2501F&btnG=Search>
has 190 pages that sell or mention the Switchcraft 2501 F connector

<http://www.stkcheck.com/evs/mfg2.asp?mfg=SWITCHCRAFT&urlpath=&urltext=&DX=&part=2501F&sty
pe=Search>
is a page of distributors with it in stock.

I can ship you one of the connectors if you want it. $3.50 plus
whatever the postage is for the padded bag. Never a handling charge.

Michael responded:

"I can ship you one of the connectors if you want it. $3.50 plus whatever the postage is for the padded bag. Never a handling charge."

But you didn't state what postage is, or address the difference between your Swithcraft products and those of a real Amphenol product. You also didn't specify what the postage charge would be.

I suppose that I'm a little more open and upfront that you. If you purchase one if these connectors from me, they will be original Amphenol products and shipping is FREE.

I take it that you are declining my previous offer. Your connectors are imitations, and their cost is not $3.50 but $3.50 plus whatever you deiced to charge for shipping. My price is at auction $7.50 with no shipping charges, and this is for original Amphenol products in shiny new condition.

What's the bottom line price, including shipping, or your Amphenol look-alike connectors?

Harry C.

Michael posted:

"As far as Paypal goes, I do not have an account. I don't buy or sell on E-bay, so i really don't need one."

So, why are you posting objections to those of us on eBay and Paypal who have earned a credible history of performance over the years. We who use eBay have no knowledge of who you are (because you have no feedback history), so you could equally be a nice guy or a scam artist. If you don't want, or don't have an eBay history, and are selling items on the Internet, chances are that you are some type of scam artist, and put-down those that would otherwise (based on their established history of good dealings) pose a competition for you.

On eBay, before sending any seller money, most of us will look up his/her eBay history. This tells a lot of information, and trust. Not having a history on eBay, were I to send you $3.50 for one of your connectors, I would be taking a risk...but not a large risk since the amount is only $3.50, Were you no a listed and registed seller on eBay, I wouldn't send you anything...except in this test case...because you have no established credibility. Same thing holds true, if you don't have a certified address on Paypal, in which case I can send you nothing.

You have evidenced a very loud mouth, and evidently decline my posted challenge. So....please go away!

Thanks Tom,

I've followed lowfer technical discussions for some time now and
thanks to some recent input from a few of them, I have a much better
idea of what I need to do to get a decent antenna up.

My plan is to have a single turn or 2 turn centertapped loop, each
side being 10 to 12 feet long and the turns spaced 5 inches apart. The
conductor will be 200 A aluminum service entrance cable which I have
laying around.

The impedance of this antenna will be low and the Q should be quite
high, with lots of area, so it should drive the receiver well.

It has occurred to me that the antenna itself has a great deal of
selectivity, yet some loop users still report front end overload from
AM broadcast band and other megawatt LF rf sources.

The QSD is susceptible to harmonics also, so a very high attenuation
low pass filter is the minimum filter necessary to keep these signals

out.

Whether the tuned antenna by itself is adequate, I don't know.

But, I'm considering putting in a bandpass or low pass filter designed to match the lower impedance loop antenna directly, so the filter would have input and output impedances of 5 or 10 ohms.

Anyway, that's a topic for another day I suspect.

Regards and thanks for the input.

Hi Joe,

It appeared to me that the transformer was used as a convenient means
to introduce 1/2 of the Vcc to provide DC bias equally to each of the
4 switch inputs.

The 10 ohm series resistors look like a resistive impedance matching
scheme to me, with a built in 6+ db loss associated with them.

I'm thinking of redoing the entire input circuit to take out hte
reistors and to better match the lower impedance of most VLF loop
antnnas.

Thanks for your comments.

I am not COMPETING with anyone for sales. I don't care if the parts
I have ever sell. When I die whatever is left will be going to the local
landfill, rather than let them go to someone who will sell them on
E-bay. I don't buy on E-bay because I have more projects and parts
left, that time to finish the projects and use up the parts. Also,
almost all of my spare money is going into a non profit corporation to
help local disabled veterans. I collect and repair old computers for
vets who are too poor to buy a computer. I would rather do this than
put up with the shit I get from hams these days. Why subject myself to
it when I can work when I am well enough, then call the "Vets helping
Vets" to tell them that another free computer system is ready for them
to give away? Do you do anything for your fellow humans?

I have no objections to anyone who buys or sells on E-bay, or uses Paypal. As far as a loud mouth? It is you who refuses to admit that Switchcraft is a quality product. I am 100% disabled, after 40 years of working in electronic repair, Broadcast and CATV engineering. I spent my last four years working at Microdyne building $20,000 to $80,000 telemetry receivers and systems. I really don't care what you think.

Hi Tom,

I think the loop antennas are pretty quiet compared to wire antennas
and you might need some gain.

But, since the antenna is high Q and tuned, it might have enough
voltage output to drive the soundcard more or less directly.

I don't know for sure.

But, if the switch is anywhere near linear, you would not want your
gain stage before the switch, would you?? I can't see using an rf amp
at the antenna that just creates non linearity when you could use a
nice quiet audio amp op amp on the far side of the analog switch.

An all software based receiver shoulnds like a neat idea until you
realize you run out of dynamic range by trying to sample such a wide
bandwidth directly.

I think the analog switch (hardware) is here to stay, at least for
ashile.

How do I know what the shipping will be if I don't know the zip code? I provide the mailer and label, then pass on whatever the post office charges me. No more, or less. I have sold parts to a small number of people online, in different news groups, and to people that found some rare ICs (NEC MC-5800) on my website. I have sold a number of parts to guys on news:rec.antique.radio+phono

> I suppose that I'm a little more open and upfront that you. If you

> Amphenol products and shipping is FREE.

I have a few Amphenol microphone connectors, somewhere. The insulators were soft, and the plating was poor on the center contact so I just don't use them. The springs were easily damaged as well. In fact, I replace them with Switchcraft.

$7.50 and free shipping VS $3.50 and probably $1.50 for shipping. Hard choice.

I used to ship the parts and let people send me a check after they received it, but no more. For years I had no problems being paid, then all of a sudden no one sent a check, unless it bounced.

What is the zip code? I will find out tomorrow what it will cost. Not that it really matters. You will find fault with anything I send, just so you can be right.

BTW did you even look at any of the links I provided with pictures of the connector I have? I doubt it, or you wouldn't have such a pissy attitude.

I doubt that you will respond with your zip code, because you just want to bitch about something. You call me names yet I have NO idea who or for that matter what you are, Harry.

There are easier ways to introduce the bias than to add transformers. Personally, I hate transformers and go out of my way to avoid using them but sometimes they're a necessary evil.

I'd venture to say that the transformer in this implementation of Tayloe's detector was introduced to:
1) Improve second-order distortion performance
2) Eliminate the need for differential amplifiers at the output
3) Attempt to skirt some patent issues.

These are just my opinions...I'd like to hear different points of view.

As to your redesign goals, be aware that the input source resistance is an important part of the inherent bandpass response that this detector has. It's based on commutating filter principles.....you can read up on this by doing a web search. The resistors were probably added to stabilize the selectivity performance in the face of variable antenna impedances. The resistors will add a little to the insertion loss and thus the system noise figure, but this will probably not be an issue at LF frequencies where atmospherics and man-made noise dominate.

Overall, I think this is an outstanding detector for an LF receiver. You should be able to get very good quadrature LO phasing using the common & simple Johnson counter approach. Once you get to quadrature detector outputs, an audio frequency DSP should result in a very good receiver. As you probably know, there are several public-domain DSP software packages available for both Windows and Linux that will do a very good job for you.

Joe

> An all software based receiver shoulnds like a neat idea until you
> realize you run out of dynamic range by trying to sample such a wide
> bandwidth directly.

In another reply to this thread, I mentioned commutating filters. At VLF, one of these ahead of a good ADC would probably also yield very good performance without downconverting to audio baseband first. As to speed of the ADC, using undersampling you theoretically only need enough speed to sample at twice the modulation (information) bandwidth. This is just a few kilohertz sampling rate. I've heard of this technique, but don't recall ever seeing it implemented in a real receiver design.

Can anyone comment and shed more light on this??

Thanks, Bill. I haven't shipped anything in about two years, so I had no what the rate was. I don't know for sure what the connector weighs, off hand, but should be about the right range after its packed. My digital postal scale only measures in quarter pounds so its only useful on heavier items.

I recently tore another microwave oven apart for the two really-strong
magnets that are in the tube

(they are fun to stack alternate-polarity on a wooden dowel
so they seem to "float" in the air; kids of all ages just
love to play that that "toy")

(I kept the transformer, diode, capacitor, and misc. microswitches, too),

and as I carried the rather bare chassis out to the garbage-can area,
I wondered if anyone had ever tried built an amplifier in such a chassis
-- maybe even using some of its many interlocks?

Look for "antenna effect". Most likely the broadcast signals are
connected directly to the pickup wiring, which works then as an
ordinary "electric" antenna.

One way would be to make the pickup loop of coaxial cable. Bend the
end of the cable back to a convenient place on the cable to form a
loop, solder the end (both centre connector and shield) to the shield
at that point. At the opposite end of the loop cut the shield and now
you have a nice electrostatic shield around the centre conductor.

If you use a huge amplification on a single frequency, you can end up with stability problems, due to unexpected feedback paths, such as a direct conversion receiver with a lot of audio gain started to oscillate, when the loudspeaker sound vibration was connected back to some front end component that was microphonic.

Putting a (possibly switchable) preamplifier between the selective loop and the mixer would allow some gain to be done at non-audio frequencies, thus, reducing the risk for stability problems.

Hello,
I have lots of power mosfet (IRF640, 740, 840 and similars), I'd like
to try
to build a power amplifier for 50 MHz (even 100W CW is ok), what
parameters
of these mosfet can tell how high they can go in frequency? I've only
seen
some projects for HF bands with these kind of mosfets, so probably
there is
a good reason not to try to go higher. I think fall and rise time give
the
limit, but what else? Also, the datasheet of these devices don't have a
table of Zin and Zout, so how one is supposed to calculate them?
Thanks in advance for any hint.

Good luck. Most of those devices will exhibit gain to amazing
frequencies due the fact that fets have no real limits like junction
transistors. What they do have that limits them is real world things
like lead inductance, Input capacitance, output capacitance and Drain
to Gate Miller capacitance all of which make it difficult to get power
in and out of them as frequency increases.

The input capacitance for the IRF510 is 135pf, the higher power parts
can easily be upwards of 1275pf for the IFR640 (Xc of around 2ohms).
Output capacitance around 400pf and feedback capacitance of 100PF
also for the 640.

I have driven an IRF510 at 50mhz and gotten 4.5W out of it. To do so
I had to drive it as a 5 to 10ohm very reactive input, use a 24V
supply and load the output to around 10ohms, and bias it for 100ma
minimum. It was unstable thermally(tended to runaway toward device
burnout). The output spectrum (harmonics) and IMD were poor.
At 12V power out was nearly RF power input.

It was more effort than driving a 2SC1307 (old cb final) at 12V, more
gain and the IMD was better. At 12V the 1306 gave 6W carrier power
with good stability. A pair of 2sc1971 driven pushpull easily give
10-11W carrier at 12V and are fairly clean.

There are FETs characterized for RF power but they are not inexpensive
and corosponding bipolar devices are fairly cheap.

I haven't been on a vacation in over 20 years because I couldn't
afford to take the time off, and had any money to spend at the same
time. The last few years that I was ale to work I was on the advisory
board for a local school system's vocational electronics course. I would
take vacation days to go into the classroom to help the kids that wanted
to learn, and give the an idea of what to expect in the real world of
electronics. Now, my disability pension is below the poverty level and
I don't get any retirement benefits so I continue to live a very simple
lifestyle. They tell me I am allowed to earn a little money from a
hobby, but no one will give me a dollar amount. Others tell me to take
in boarders. That will not only cost me my pension, it will kick my
property taxes up to more than I could make by renting out the extra
bedrooms.

As far as giving computers to needy kids there are at least a half dozen groups already doing that in my area, so I chose to help another group that was in need. The disabled vets don't care how old a computer is as long as they can do e-mail and some simple browsing. After all, most of them are confined to a wheelchair, or bed and have nothing else to do but watch TV.

The needy kids that I have talked to wanted a better computer than what I use for myself, and to track the project. They also want a printer, a scanner, a cd burner and a DVD drive along with plenty of paper and ink jet cartridges. Several insisted that they had to have a laptop and that a desktop computer was useless to them. So far I have only had one laptop donated. It is an old Compaq that has a failing display and a dead battery. Who wants to spend several hundred dollars to repair a Win 95 laptop? We all have choices to make in life. Since I am a veteran who is disabled, and I chose to help my fellow veterans, and I applied to join the DAV last week.

Have fun selling on E-bay. I can't afford to play the games a lot of people want on E-bay. I see things that ask three times what something is worth for the shipping costs. Add in their minimum bid and I can buy two to four of the same item, brand new for the same price, and have them delivered to my door.

BTW, I guess that you didn't know that Raytheon owned Switchcraft? I don't know if they still do, but it was clearly marked on the cover of the last printed Switchcraft catalog that I have.

Source record: 17192

Hi T,

I think you missed the point. With a tuned antenna, what comes out of the antenna+tuning is NOT broadband! Frequencies not so very far from the one you are tuned to will be greatly attenuated. With that sort of input, you should be able to get by with even a 16-bit converter, if it's linear (such as a decent delta-sigma is).

For example, a square loop antenna one meter on a side, at 150kHz, tuned to resonance with a capacitor, should have a Q around 300. That means it's about 0.5kHz wide at the 3dB points, and will be down about 20dB at 2.5kHz away from center, and 40dB down at 25kHz away.

-- I just read your other reply to my other posting in this thread, where you worried about broadcast band overload. I suspect that if you have that, it's because, as someone else said, the antenna is acting as something other than a loop for that frequency. It's important to keep the loop balanced with respect to ground. I'd strongly recommend against a "shielded" loop unless you understand just why you are doing that. The shield becomes the antenna, and as such, it must be symmetrical... Also, for the antenna you described, about 3 meters on a side and large wire, expect the Q to be even higher and the bandwidth narrower. I think you'll find the resonated impedance to be more like a few kohms for a single such turn. Then, use a good balanced FET amplifier to get to a low impedance to drive your transmission line.

By the way, I would note that the switching detector/mixer/converter in the schematic you showed is not as good as the usual current implementation of the H-mode mixer, because the channels of the FETs doing the switching in the one you gave a link to operate at a voltage which depends on the instantaneous signal amplitude, if I read the schematic right, and since the channel resistance is a non-linear function of that voltage, the detector will not be strictly linear. The H-mode mixers operate one end of the switches at a constant voltage, and of course the other end when the switch is on must be very close to the same voltage. I expect (and I think the practical experience is) that the H-mode mixer will be more linear. Do you know what the third order intercept for your mixer is supposed to be? I'd be pretty surprised if it was better than about +45dBm.

But even so, even if you DID have a broadband antenna, you can find op amps, and you can make amplifiers with discrete parts, that have distortion products more than 120dB below the level of signals in excess of a volt at the amplifier output, in the LF frequency range. In other words, the distortion products will be less than a microvolt, with one volt output signals. You don't need to run that preamp with

any appreciable voltage gain, so you're handling some pretty big input signals. And the best of the 24-bit delta-sigma ADCs shouldn't be far behind that. (I wish I could do that well at 50MHz!--we do make a 23-bit ADC that samples at up to 20MHz, but it's a bit pricey for what you're trying to do.) As others have pointed out in this thread, the atmospheric noise is so bad at LF that the antenna doesn't have to be very efficient to capture enough signal to be useful for receiving. Unless you are practically next door to a transmitter operating on a frequency near the ones you care about listening to, dynamic range isn't likely to be a big issue at LF. [Your other posting suggests that folk DO have troubles with other signals. I'd go looking for answers about WHY before jumping to conclusions about what to do about them.] That's a far cry from the case at HF.

Cheers,
Tom

4210. Big old-fashioned IF transformers for tube-type homebrewing?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-09-14 00:08:48 UTC

Source record: 17193
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

Are the big old-fashioned IF transformers-in-a-can available
anywhere anymore? I want to make a receiver, probably double
conversion,
which would mean that I'd want several each of the 50kHz and some
higher frequency (455kHz likely).

Are these things that can be made from scratch without a lot of
difficutly? I can wind coils etc. but don't
have any transformer slug-tuned cores.

4211. Big old-fashioned IF transformers for tube-type homebrewing?

Newsgroup: rec.radio.amateur.homebrew

Are the big old-fashioned IF transformers-in-a-can available
anywhere anymore? I want to make a receiver, probably double
conversion,
which would mean that I'd want several each of the 50kHz and some
higher frequency (455kHz likely).

Are these things that can be made from scratch without a lot of
difficutly? I can wind coils etc. but don't
have any transformer slug-tuned cores.

No, but the tube runs at a freq real close to ham Slow Scan TV bands.
They retune them and use them as SSTV transmitters.

YES. Almost every hamfest that I attend in the Chicago area has a gentleman with 455 kHz IF transformers like we are use to seeing in older tube designs. I also had replacement 10.7 MHz units for the older FM tuners. Check with the surplus houses for units.

Hi Tom,

I read your message above about 3 times now AND read all the other posts in this thread over again.

After all of this, I must say that I'm very much in agreement with you although I know little about the linearity of the particular analog switch used in this configuration.

When I started this, I was paranoid about out of band signals mixing and creating problems. Read posts from almost anyone using an LF preamp or presenting a design for one and they will almost certainly contain warnings about overload and mixing byproducts.

So, I wanted an almost unattainable filter on the front end, without realizing in fact how much attenuation the antenna I hope to build will have for out of band signals. You are exactly right, there is probably no need at all for a tuned input in the receiver since the antenna tuning will be so sharp.

Maintaining HI-Q in the antenna should be the primary goal I think rather than worrying about the input filter parameters!

I disagree about the rf preamp however, Bill Ashcock says I shouldn't need one at all as long as I keep the Q high in the antenna and feed it into a balanced line to get to the shack. Bill says some of the guys who have single turn loops 40 feet per side or larger have so much signal, they have to attenuate. I'd like to start out without a preamp unless it is really needed.

By the way, the antenna might not be balanced.....but if it's fed through a balun on each, the feedline is balanced. And, the feedline can be simple twisted wire pairs....which goes a long way towards reducing stray rf pickup and makes the feedline cheap and the losses

low.

If I feed the antenna into a balun and run that to another balun at the receiver, isn't that the same as having a traditional center tapped loop in terms of 'balance'?

I'll try to find some software for loop design and see what the loop looks like in terms of impedance and then decide how to couple that directly into the receiver without a front end filter (just simple impedance matching).

Thanks so much to you and everyone who wrote regarding this, and for the nudge in the 'right direction'. I feel a lot better now regarding the plan of attack than I did just 2 or 3 days ago!

Regards,

T

PS:I like your estimate for my loop impedance. If it's 1000 ohms as you think it might be, I can handle that step down just fine with a balun or 2.

I hope it turns out to be true:>

Hi Tim,

They are homebrewable. I needed a few 455khz for a tube RX I was
building and basically resused some old "IF like" cans by replacing
the guts with handwound coils and caps. The forms for the coils were
Horz width coils from a few dead monitors, used the slugs too. Used
one of the basic programs for solonoid coils to get a rough number of
turns and then then wound 30% less in scramble form. That gave a
basic coil and then resonated it with a cap to 500khz. Once the slug
was added it easily tuned down to 400 so I cut the slug shorter (1/2)
and it was fine for 455. The distance between the two coils (for
double tuned IFs) determines the coupling factor, or more directly
the selectivity and losses. Once you have the recipie for one winding
you can easily reproduce it.

Theres nothing special about IF cans save for they have to tune the
desired range, have a decent Q and are shielded. The outer can
however is important or that IF amp will become an IF osc. But even
the can can be liberated from salvage or made from copper, tin or
aluminum stock. I made some really nice looking cans using 1"
Copper pipe and pipe caps, heavy but well shielded. Soda straw
was the coil form and holes in the ends supported it and allowed
access to tuning slugs. Leads came out using insulated Teflon
feedthroughs. Looked very industrial.

Most power MosFets have a large Gate to Source capacitance which makes it difficult to use them at radio frequencies.

It can be done, but the higher the desired operating frequency the greater effect the parasitic capacitance has, so most designs I have seen were up to 7 MHz and that was about the upper limit.

They are a bloody pain. You should try it. If it was easy, it
wouldn't be fun.

With some kind of vertical antenna (possibly with some capacitance)
which is small compared to the wavelength on LF, it is going to have a
large capacitive reactance. There will also be some antenna input
capacitance from input to ground, so essentially there is a capacitive
voltage divider formed by the antenna capacitance and input
capacitance and the amplifier is trying to tap off that voltage. So
the amplifier really needs current gain, not voltage gain i.e. a high
input impedance and a manageable (50 ohm etc.) output impedance.

A German ham radio magazine just published a project for a 400W MOSFET PA
covering the 80...20m bands:

Reading from the ARF488 datasheet (this mosfet is made for RF
amplification
up to 60 MHz or so) I see input capacitance of 1400 pf typical, and
150 pf output capacitance typical.
The IRF840 datasheet reports 1300 pf and 200 pf in/out capacitance
at the same frequency of the ARF488 (1 MHz). So what else affect
high frequency performance of these devices? Is the 50 pf difference
in output capacitance the "big" problem? Reverse transfer capacitance
of the ARF488 is 65 pf against the 18 pf of the IRF840.

what do you suggest on the bipolar side to obtain at least 100W CW
on 50 MHz? Monitor line output transistors are any good?

Thanks and 73

Yes that is true. However that input capacitance is close to what I'd
use to bypass a 50mhz circuit. It's near RF dead short unless you
try to absorb it into the feed network. Even then it's a very low Z.

All I can say it try the most likely candidate. They are designed for
switching power at a few hundred KHZ.

Best results will require a 24V or maybe a 40-50V power source.

MRF492 is a good 70w device I've had good success with. If you can
afford it MRF141 RF power fets or MRF150 but they are expensive.
There are a number of 2SCxxxx part numbers that also would fit the
need but experience with them is limited.

If all else failes a Valve such as a 4cx250 with 800-900V on the plate
would do 100 or more watts out.

Allison

7mhz was not the upper limit but around 20m the Gate Xc does makes
them harder to drive.

There are a number of designs that run them as linear amps to 10m but
the drive networks take that into account. A pair of IRF510s will do
35-40W in the FARA design published in QST.

Yes but were they class E or linear? There are a number of AM ops on
160/75/40m running 1kw AM phone using class E FET. However class E
for 6M I havent seen yet. The german design would not run at 6m and
thats what the initial posting asked for.

Those power fets at lower frequencies are a very useful devices but at
VHF their characteristics are difficult to accomodate.

Yes, I understand it. What isn't clear to me is why the ARF488 is
specified
for > 60 MHz and has input capacitance > of the one of an IRF840.
On QEX of may/jun 1999 you can find a 300W 50 MHz amplifier with
ARF488 push-pull.

I should have a couple of 4cx150 around, but this amplifier should
sit right under the antenna in the same box with a receive
preamplifier.
I was trying to avoid a big tube ampli. And also I was trying to
recycle
"normal" components, which is also a good way to learn something.

I'll check that one out. I do not have QEX back to '99 so it may take
a while to get it.

I suspect the ARF488 is a RF rated varient of the IRFs and may offer
other characteristice that are more complient at VHF. I cannot find
any data or even a reference to ARF488.

I am a 6m op that love to play on that band so curiousity always wins.

Buy a couple of beatup Command sets or other mil surplus and salvage. You
can always get 455Kc IF xfmrs from old tube radios. Making your own is too
much work, so salvage and spend that extra time on making a better radio.

Getting the bandpass right could be a pain; I'd guess the
sweet spot is near critical coupling, where you'd get a
double-humped response curve. Otherwise, undercoupling
would give you a sharper peak, good for CW, or you'd have
to sweep align the strip for the desired BW.

One thing I haven't heard mentioned is that the huge capacitances of power FETs are highly variable. They're essentially reverse-biased junction capacitances, so they change dramatically over the period of each cycle as the gate and drain voltages change. This tends to make them lossy, and makes them difficult or impossible to absorb them into a network. People have obviously found ways to live with the variable C, but it's not a trivial problem.

Roy Lewallen, W7EL

4233. DDS and phase noise.

I'm not an expert and need some help.
I've build a DDS around an AD9951.
I drive it at 400MHz from a source at 200MHz multiplied by 2. I get an output freq of 20MHz.
I now drive it directly from the same source at 200MHz. I changed the register inside DDS to still get 20MHz on output.
I do not have any possibility to measure the phase noise.
So the question: is it possible to estimate if the phase noise of the 20MHz output is getting better, worst or is it going to remain the same?
Thanks for the support.

Switching power MOSFETS are the current version of the "sweep tube"
amplifier. Looking back those 6DQ5s and 6JS6s werent pretty either.

Roger that, they are no fun to drive. The miller capacitance is also
a similar factor and you have the same effect going on from the Drain
Source path becuase of the avalanche diode. I suspect those
combined effects are why the IMD for those single ended IRF510
amps are so pitiful.

Driving them as pushpull pairs helps somewhat as you can get one
and the other 180 out of phase to help reflect a passable reflection
back to the driver.

Decreasing the frequency at which you clock the DDS will increase the phase noise. It is pretty hard to estimate as it will change quite a bit with small changes in divisor (i.e. output frequency). But as a general rule, you want to clock the DDS at some high multiple of the operating frequency.

Obviously, if your clock has phase noise too, that is a bad thing. I would doubt that your frequency doubler would add phase noise, but I can't say for sure since I haven't got your circuit. But typically doublers introduce other forms of distortion which aren't as problematic for a DDS clock.

So just shooting from the hip, I would expect your phase noise to be a lot worse from a 200 MHz clock than from the 400. It is still 10x the operating frequency, though, so I wouldn't expect it to be horrible.

There are 2 main sources of phase noise in the output of the DDS: The
residual noise of the DDS and the divided down noise of your clock source.

The residual noise is inherent to the DDS and not dependent on the clock. It
is a function of the technology used to build it. This should be specified by
the vendor. It is usually measured by driving 2 identical DDS's from a common
source, measuring the resulting phase noise and subtracting 3 dB to account
for 2 devices.

As for your clock noise: Your 200 MHz clock noise will be increased by 6 dB
by doubling [plus any residual noise of the doubler -- use a Schottkey diode
doubler for best results]. That 6 dB will be subtracted by the extra factor
of 2 in the effective divide factor of the DDS. In short -- its a wash except
for the doubler residual noise reduced by 26 dB [20*log10(20/400)] which
should be insignificant.

The groups dealing with kids around here tell me that they have to have to have internet access for their school work. They asked for more than I can deliver, so I turned my efforts elsewhere, and left the other groups to help the kids. They already have every computer store in the area giving them everything, leaving nothing for others who need computers. My efforts are limited to an occasional mention in a weekly "Bulletin Board" column in the local news paper, and what Vets helping Vets has dropped off at their office.

My church is trying to raise the money to buy and set up a used double wide portable classroom to teach free computer classes after school. The people giving computers to kids do just that, and walk away. The classes will start with the basics, then cover safe browsing. Classes for the kids will be right after school, and another session for adults in the evenings. Our recent work to help relocate refugees from Mississippi to this area have set the project back quite a bit, but it will happen.

A smaller computer repair course will be offered to selected students who show an interest. It will be four hours a day on Saturday mornings to make sure they really want to take the course. I hope to take most of them to the point that they can pass the A+ certification at the end of the course.

Assuming your source is not so good as to be below the noise floor of the AD9951, you will get slightly better performance without multiplying by two. The rule-of-thumb for perfect conversion is 6dB for each doubling. But it won't be perfect, so by doubling you'll be a little worse than 6dB and then dividing again you will not get as much back. If the doubling was perfect and the performance of the AD9951 was the same at 200MHz and 400MHz, you get the identical results.

Of course, this might be bogus if there are other artifacts.

Make sense?

If you can build a doubler, then you can measure phase noise. Mix your 20MHz output with a known good 20MHz source in a double-balance mixer. Adjust the phase to get zero DC (quadrature). If you low-pass filter the output, the noise is an indication of phase noise. If you have a low frequency spectrum analyser available, you can get a nice plot. Otherwise you can use an AC voltmeter to get relative performance.

I can't be held responsible for top-posters.

If you'd paid attention, the post I replied to was a top post, and he
was referring to the nonsense reply to the original post.

Note I specifically said "reply", as in
" No, but the tube runs at a freq real close to ham Slow Scan TV bands.
They retune them and use them as SSTV transmitters."
which makes absolutely no sense, since SSTV is commonly used on HF.

I wasn't asking about re-using the microwave TUBE but the CHASSIS and
maybe the interlocks and the cooling fan (I forgot to mention that in
my original posting). If the new RF tube(s) would fit, the shielding
at HF should be superb(!), yet one could still see the warm glow of
the tubes through the grilled door.

I can send you both the QEX article and the ARF488 datasheet (also the
IRF840 one, but this is really easy to find in the internet). Just
drop me an email and I'll send them, my email address is the one I'm
writing from.

same here. I've found that my 10W CW aren't terribly effective even with
the 8m boom yagi lately, so I'm thinking about something more powerful
while the sun is sleeping. Seems like the old days when I could hear
and work VK with a J-pole are gone.

> One of those 4cx150s will do over 100W CW and the PS for that power

Also these tubes need forced air cooling and the power supply would need
to live near the amplifier (unless I want to send a cable with a kV up
to the antenna pole), if the mosfet way fails I'll probably go with an expensive
bipolar amplifier or put the amplifier in the shack.

You can find a good program to estimate loop inductance and some other parameters on Reg Edwards' web pages. He has a link in many of his postings on this group and the r.r.a.antenna one. The impedance comes from the Q and the fact that you are resonating it--or at least it's presumed that you are resonating it. So if it has a Q of 300 and the inductive reactance is 50 ohms, the resistance when resonated is 300*50=15000 ohms, for example. That's why folk like to use preamps at the antenna: transform that high impedance down to a low impedance that's easy to send along a transmission line. Seems to me that if they are having trouble with intermod distortion in the preamp, the preamp isn't designed properly. It's not terribly difficult to get very low distortion at LF these days. By the way, if you build a really big loop and have so much signal you can attenuate it, that gives you a chance to lower the Q and increase the bandwidth: if what you want to listen to occupies much bandwidth, you don't want your antenna to filter out the information you want to listen to!

I'd suggest you read an antenna book like Johnson and Jasik, or the antennas chapter of King, Mimno and Wing's "Transmission Lines, Antennas and Waveguides." They will make it a lot clearer why you might want a balanced loop. You don't need a grounded center-tap to make it balanced--just make it very symmetrical.

Cheers,
Tom

There was a fellow in Central Ohio in the late 80's that used a
microwave oven as a fast scan TV transmitter on 2.4Ghz. The details
are very hazy in my mind and I don't recall actually seeing his
signal.

He started with a new unit from a discount store. Feedline losses were
a major problem, he eventually put the thing on top of the tower.
Needless to say, experimenting with a tower mounted transmitter can
bring a whole new set of problems. Especially one that heavy.

I don't want to discourage tower mounting though. About the same time
I had a QRP ATV transmitter at 1296mhz at the tower top that worked
well.

Yes, I found it day before yesterday and was stunned to see the loop impedance change so much as the loop is moved off frequency. I want my antenna to cover 50 Khz to 200 Khz and the antennas impedance will vary from 6K ohms to 1 K ohm, quite a LARGE range.

The software was very helpful and enlightening.

I was hoping to feed the antenna to the house over twisted pair line laying on the ground. This requires a balun to make the low impedance line balanced.

I think the antenna should be balanced as well, which helps in elimination of out of band signals that might overload the preamp. I think, but aren't positive that the balanced antenna is necessary to eliminate the 'antenna effect' which allows the antenna to pick up other signals that it wasn't designed for just because it's a piece of wire hanging in free space.

So, my plan was to build a balanced loop and feed it to the house with a balanced feedline.

It's not likely that I will ever want to listen to SSB or any other wider band modes, but I did consider putting in a resistor to kill the Q if I ever wanted to do this.

>

No, it's pretty clear that I want a balanced loop. Several lowfers
made strong suggestions that I should not waste my time building
anything that wasn't balanced, and I couldn't agree more.

>Cheers,
>Tom

Tom, I hope to put up a high Q, but relatively large loop. I expect to
have a very large signal output to the receiver. Signal strength of
received signals will probably NOT be an issue.

Because the signal will be relatively high level, I would like to
resist using a preamp at all.

While I was playing with filters last night, I tried to design a
filter that would also convert impedance from 6 K down to 100 ohms. It
became impractical with a balun BUT, a filter that transforms
impedance seems to kill 2 birds with one stone.

However, performance sucks real bad with filters of higher impedance
and with any filter that attempts to make a large or moderate
impedance transformation.

Is there any other means of converting impedance with out an active
amp (using passive components)? Since I have a big signal, I can
sacrifice some signal strength as long as the losses are not to great.

Maybe I should start another thread?

Regards,

T

>I can send you both the QEX article and the ARF488 datasheet (also the
>IRF840 one, but this is really easy to find in the internet). Just

After looking at the data sheets and the apnote it confirms what I've
said.

The APT/ARF488 is a RF device and not close to the IRF parts. One
difference easily noted is the lack of the avalanche diode present
in the IRF parts. It's appearance spec wise is that of a low cost
flavor of currently know RF types without the high cost package.
I may add the ARF488 is unobtainium, apparently they have
discontinued it and gone to newer versions.

The apnote confirms the need for elaborate input match for a rather
low input impedence that is highly reactive. The 50Mhz amplifier
is not broadband and for 6m would be classified as very narrowband
with it's specs covering on the 50-51mhz range. Their use of
striplines to affect input match and output match contribute
to the narrowband behavour. It is a high power amp at 300W with
an IMD3 of -25dbm which is only ok, not great. You also need an
85V supply and have to deal with cooling both the supply and
the amp.

You could try an IRF parts in that circuit but read the apnote well
as it explains the problems and techniques applied to overcome
those problems at 50mhz. However the values required ot match
the IRF vs the ARF parts may vary greater than the design limits
resulting in poor performance.

Source record: 17233

Yes, this might be good for another thread...

Given the limited LF bandwidth you're interested in, I can't imagine that making a transformer would be all that difficult. Not trivial, certainly, but far from impossible. A 5:1 turns ratio will give you a 25:1 impedance ratio. You'll want to use a core material that doesn't introduce distortion. A transformer like that also gives you a way to keep the loop loading balanced. But--are you going to put the tuning capacitor at the loop, or do you have in mind putting it, say, at the receiver end of the feedline? If it's at the loop, how will you adjust it? And just what size signals do you expect to get? One of the nice things about LF/VLF is the predictability of signal strengths. Also, beware of worrying a lot about feedline impedance. How long will your feedline be, in wavelengths? If it's, say, 0.05 wavelengths at 100kHz (and THAT's 150 meters long!), does it really make much difference that it's quite a different impedance than the antenna? And...what IS the impedance of the line, at that frequency? It may well be a bit different from what you calculate for the line at 10MHz. What would happen if you fed your one turn loop with 100 feet of "300 ohm twinlead" or "450 ohm ladder line" and just tuned it at the receiver with a capacitor across that line? Small transmission line wire size would ding the Q some, but would that be an issue? I'm just speculating here, and maybe someone with direct experience with that sort of feed will offer suggestions.

One thing to keep in mind here is that the LOOP construction will almost certainly be the most challenging and expensive part, for a big loop. And--you may really not NEED THAT big a loop! More signal also means more atmospheric noise, and you won't improve signal:noise ratio just by getting more of both signal and noise. Anyway, once you have a well-constructed loop, it's relatively easy to play around with different feed systems--preamp and remote tuning, straight feedline, whatever.

Cheers,
Tom

From what I've seen in the data sheets, the closer you operate the RF output to the Nyquist limit (Fref/2), the cleaner the spurs get. I've seen numbers of -90 dB or better on even some of the cheapo Analog Devices parts.

Thanks to all who replied.
I think that the net is that the phase noise should remain about the same.
The source is a low noise quartz oscillator based on J.Stephensen design,
followed by a Schottkey doubler and a MAR5 amplifier.
I was in doubt to use or not the Schottkey doubler. I think i'll keep the
simplest solution: no doubler.
DDS max output will be 39MHz. A reference clock of 200MHz is still about 5
times the max output freq, high enought above the Nyquist limit.
Thanks again.

OK, I just ran some numbers for a 6000 ohm to 100 ohm toroid
transformer at 190 Khz. I didn't have to deal with the secondary at
all, because the primary has to be so large...I never made it past the
primary! Perhaps I made an error in the calculations? The transformer
has to present about 6000 ohms of inductive reactance, which is 16.6
millihenrys. Even on a large high mu core, I'd have to wind 400
turns!!!!!!!!!! With that many turns, the losses would be big, and
would still have to wind a secondary (although it would much much
smaller). Did I make a mistake in the calculations?

I don't mind going to the antenna to tune it-lowfer signals don't
change frequency much.

>Also,

>

Was hoping to use twisted wire which can be homebrewed or cat 5...it's
cheap and available. I think the twisted wire runs 80 to 90 ohms
impedance. I considered that I might just tolerate the mismatch since
the run was so short....but it's such a big difference, I am not sure

the input filter in the receiver will react as expected.

>One thing to keep in mind here is that the LOOP construction will
>almost certainly be the most challenging and expensive part, for a big

>different feed systems--preamp and remote tuning, straight feedline,
>whatever.

Are there any other ways to convert the impedance without big losses
or without resorting to an active preamp? I'd like to avoid the preamp
if possible, especially since I expect a good output voltage from the
big and relatively high Q loop.

Dear all

As a hobbyist I am looking for advice re online PCBs
Have not done any electronics for a couple of years. The board house I used to deal with locally has closed.
They produced V good quality boards, but obviously couldnt compete with cheap Taiwanese/Chinese producers.

I use the old Protel Autotrax circa 1991 - no interest in paying $3K for the latest software.

I want
good quality for SM packages to TQFP
Mask/overlay
Small runs up to 50 or so and prototypes
2-4 layers
will accept Protel Autotrax as a format

What do people use?

Thanks
Richard

The AD9951 has a much better spur performance than earlier DDS chips, and
I have been tempted to use one for an LO in a radio, it looks clean enough
to work nicely.

==========

Generally, I'd say your phase noise will be the same either way, and
perhaps even a little quieter with the 200 MHz clock. The internal
reference multipliers probably add a little phase noise, multipliers usually
do add a little extra noise, not than the normal 20log(N) one might expect
from theory.

Reference multiplers DO allow running the DDS output to a higher
frequency, which is often a major desing goal, but if all you want is 20 MHz
output then you are fine with a 200 MHz reference.

Well, the 8:1 turns ratio transformer at
http://www.jensen-transformers.com/datashts/110khpc.pdf would almost do it for you. It falls off a bit at the high end. But with it, you could go down to less than 10Hz. That might be fun. What core material were you using in your calcs?

I really think you're being too cautious about preamps. But again, my point is that you can put the effort into the loop, put it up, and then play around with different feed methods. If you do use a feed line and leave the tuning capacitor at the antenna, you won't notice any significant loss in the line. Reg will try to "sell" you one of his programs for looking at how the line transforms the impedance, but I'd just use a Smith chart program myself. Much more educational, to me, than just seeing numbers. If you want to try tuning at the receiver end, use heavy wires in the line: their resistance adds to the resistance of the loop itself, lowering the Q. But with the capacitor at the loop, the circulating currents stay out there, for the most part. You could add a small variable at the receiver end, to do fine tuning. You may well discover that's an advantage...it's a pain to try to tune the loop without being able to listen to the signal...

Cheers,
Tom
(about to bow out of this...time for you to go try some things.)

Hello,

first of all, I just reread my original post and I've written ARF488
instead
of the correct ARF448, sorry for the mistake.

yes, indeed it's very difficult to find these mosfet today.

>
> The apnote confirms the need for elaborate input match for a rather

> 85V supply and have to deal with cooling both the supply and
> the amp.

well, the real problem is difficulty in matching and poor IMD3,
we still are restricted to the 50-51 MHz part of the band and
I don't remember to ever have heard anyone over 50.300 MHz here
in EU.

>
> You could try an IRF parts in that circuit but read the apnote well

indeed, and the diode in the IRF part could be a problem, right?

I'll probably start to search a good bipolar transistor for this project.

thanks

> What do people use?

I use ExpressPCB. I know that one of your requirements was "accept Protel Autotrax" but they don't take it.

That said, they do have their own free software (very little automatic layout but good control over things that'll matter at VHF/UHF/microwave frequencies) and I've been 100% satisfied by their service. Good prices and very quick turnaround on my hobbyist stuff, and they also do 4-layer and masks and production stuff too.

Most of my boards are a mix of SMD and digital and RF.

Tim.

The "Z-Blanking" output on the back of the HP3336 works when it goes low --
just have to match the scan time for both units and we are off to the races.
Thanks for the input.

MRF492A usually under 22$US new and good for 70W or more. There are
published designs using it that work well for all modes.

Most of the VHF power mosfets are priced around $1US/Watt it seems
and are dreadfully expensive compared to bipolars.

I'm not going to use internal multiplier. I'm driving it at 200MHz directly.
I agree that internal multiplier is adding noise. You can see that from the
datasheet.
Checked with an AOR7030 receiver the output seems to be quite clear and
sharp.
Not a real measurement, but better than some other PLL.

The AOR 7030 uses a PLL. It has a dual tank VCO as G3SBI came up with.

Try the ARRL website under TIS. It's called the "Compact 6M brick".
It was published in the OCT 1990 QST.

The circuit is very close to the Motorola test circuit for the device
with bias for linear operation.

FAR Circuits has the board for it. I think they can supply a reprint
as well.

If thats not enough power two of them with 2 port splitter/ combiners
will get you better than anywhere from 150-180W. A Wilkinsen
splitter and combiner is fairly easy to do at 6m either as lumped
elements or maybe even coax.

ISBN 0-7506-9946-9

"RF Circuit Deign"
By
Chris Bowick

Pub. Newnes.

I've just got a new copy from Ottakar's; it is
still in print (just) £21-99pp for 176 pages packed
full of concise info about RF circuits, LC filters
(especially the bits about use of an L-network to
match ant to TX) together with a good analysis of
the Smiff (That's _TWO_ "f"'s) Chart and how to use it.

This was recommended to me by my current employers (apparently
the book is held in high regard in Japan). I only
wish that I had come across it before.

Now, Brian, here's that opportunity for you to put your money
where your mouth is.....which particular parts of the book do
you "agree..... are a tad basic". Please reply within 2 minutes so
that you don't have time to consult the book (perhaps for the
very first time?), or else be seen for ever hereafter as a
laughing stock, and a LIAR.

As for employers who spot your deficiencies, who was the "south
coast defence employer" who sacked you and as the result of which
you couldn't get another job and had to go into teaching?
("Those that can, do. Thos that can't, teach, etc etc"?)

Now, Brian, here's that opportunity for you to put your money
where your mouth is.....

There are a number of rather silly and infantile people
whose first inclination is to sneer. Two such intellectual
failures are quoted below; "Empty vessels make the
most noise". A book whose first page is about
wire, the skin effect thereto, and the inductance of a short
length of wire is not basic by any means.

++

Whatever books people recommend on RF Design , as a non-professional in the
RF Field , I find :
"Experimental Methods in RF Design" by W7ZOI ,KK7B and W7PUA the 'top of
the pops'.
Published by ARRL ,it also seems to be available from RSGB.
It has more than 500 pages and costs US $ 50.-
In my opinion , as an radio amateur home constructor ,you don't need any
other RF design book , although the above book's (much older) predecessor "
Solid State Design for the Radio Amateur " by W7ZOI and W1FB (now sadly SK)
is equally inspiring .

You should already know all of the above after 30 years of hamming it up.
Basic. Looks like a good book for anyone starting out in radio with a good
basic education or a good crib sheet for the rest of us. Sitting in the sun
with a half full vessel reading Traveling wave antennas by Carlton H Walter,
includes an interesting discussion of the polyrod antenna ;c)

Hmmm. Okay. I confess that I never much used the tracking generator
since I had available an HP3577 for this kind of stuff.

That was when I was employed. In retirement I use an N2PK VNA.

I have to agree Frank, the fundamental reason why a wire has inductance is a very basic fact, I believe taught at KS3 science.

Makes you wonder about degrees from the UoE, does it not?

Now we know that you're a L.I.A.R. - the formula
to calculate the inductance of a short and straight
piece of wire simply is not taught in schools.

For someone who _BOASTS_ as much as you do about
your self-perceived importance to the world
of education, you are taking a very peculiar attitude
to the recommendation for a book to take Radio
Hams onwards. This should be an area for you to take
a lead, but your behaviour is suggestive of a loser
and not of a leader.

Sour grapes, perhaps, that you did not make the
recommendation yourself?

Does this appalling mental derangement of yours feature in
your behaviour in the classroom in Strood? Do you
sneer in the same way towards your pupils? What if
members of your school radio club were to read this NG,
what would they think of you? What would they think
of your cowardliness and laziness about the 12 WPM
Morse test and the way in which you opted for a test
aimed at 6-year-olds? Would you become as much
a laughing stock in the school as you are on here?

What would their
parents think of you if they were to peruse the
archives of this NG for the time that you were
under training at a girls' school, of all places, and
when you were publishing repeated offensive materials
about sheep shagging? Would there be an outcry? I have described
your behaviour to 3 people whom I know to be school teachers
and shown them what you published. All, without exception,
said that you are unsuitable to be a school teacher.

Your rather silly and infantile sneering below is a
further illustration of a sick, sick mind. Perhaps
it is time that you resigned from teaching?

N2PK VNA -- as this was a RSGB project I never got my arms around it --
there was a nice 100MHz VNA article in QEX July/Aug 04 by N5EG.

That you sneer at attempts to introduce Radio Hams to
materials for advancement is a very good illustration
of why anybody who holds, or who has ever held, a licence
issued under the gangrenous degeneration that is the M3/CB
Fools' Licence scheme will _NEVER_ make it into the
ranks of _REAL_ Radio Hams.

It is also an indication of by how much you have
prostituted yourself in your crusade to compensate
for your well-deserved inferiority complex - you are
the arse-licker of an irrelevant commercial book publisher
and the book under recommendation was not published by them,
and so you attempt to bad-mouth it.

As it happens, Chris Bowick wrote the book as a condensation
of his experience as a designer of professional RF circuits.
(And, no, he did not get sacked for incompetence from a "South
Coast Defence Manufacturer). He also holds the call WB4UHY (not
one of the dog-turd M3 series such as M3OSN) and lists flying
as one of his pursuits. (Wasn't that something else that you flunked
yourself?)

You are a hypocrite, sir, you have no real interest in the
education of Radio Hams unless you yourself perceive a
personal benefit of some kind.

In fact Brian, you have blundered _B-I-G_ _T-I-M-E_

Without reading it and without being aware of any
of its contents, you have dismissed, as being worse than
a schoolbook, the concise presentation of a professional
RF engineer.

Are all of your pronouncements into this NG based on
such ignorance? Are you the master of spin-doctoring,
of bull-shitting and of downright lying? Are we to take
any and everything that you say from this point on with
a pinch of salt? How will we be able to tell whether
anything you claim from now on is made up on the spur
of the moment as were your uninformed comments about
Chris Bowick's book or whether based on truth?

You silly, silly fool.

As it happens, I think that you have illustrated so
well Walt's view of you.....

It looks to be a good book for the newcomer to RF design giving readers a
basic understanding of the fundamentals, but the question is - Why would
someone with your 30+ years of experience as a real radio ham find useful?

It is, perhaps, an indication of the degeneration,
gangrenous or otherwise, that has been festered onto
Ham Radio by the RSCB, that an article such as below,
intended to introduce Radio Hams to a useful book
should have resulted in so much negative and
destructive bile.

Leon Heller is the only respondent to have been
at all positive and at all relevant.

Shame on the rest of you, CBers (Childish Broadcasters)
to a man.

Whatever books people recommend on RF Design , as a non-professional in the
RF Field , I find :
"Experimental Methods in RF Design" by W7ZOI ,KK7B and W7PUA the 'top of
the pops'.
Published by ARRL ,it also seems to be available from RSGB.
It has more than 500 pages and costs US $ 50.-
In my opinion , as an radio amateur home constructor ,you don't need any
other RF design book , although the above book's (much older) predecessor "
Solid State Design for the Radio Amateur " by W7ZOI and W1FB (now sadly SK)
is equally inspiring .

Frank GM£CSZ / KN6WH

GOVERNMENTIUM

A major research institution has recently announced the discovery of the heaviest chemical yet known to science. This new element has been tentatively named "Governmentium".

Governmentium has one neutron, 12 assistant neutrons, 75 deputy neutrons, and 224 assistant deputy neutrons, giving it an atomic mass of 312.

These 312 particles are held together by forces called morons, which are surrounded by vast quantities of lepton like particles called peons.

Since Governmentium has no electrons, it is inert. However, it can be detected as it impedes every reaction with which it comes into contact.

A tiny amount of Governmentium causes one reaction to take over four days to complete when it would normally take less than a second.

Governmentium has a normal half-life of four years; it does not decay but instead, it undergoes a reorganization in which a portion of the assistant neutrons and deputy neutrons exchange places.

In fact, Governmentium's mass will actually increase over time since each reorganization will cause more morons to become neutrons, forming isodopes.

This characteristic of moron-promotion leads some scientists to speculate that Governmentium is formed whenever morons reach a certain quantity in concentration. This hypocritical quantity is referred to as "Critical Morass." You will know it when you see it.

When catalyzed with money, Governmentium becomes Administratium, an element which radiates just as much energy since it has half as many peons but twice as many morons.

If that is your admission that it is your intention
to stir things up, then your behaviour is shameful.

Is it not enough for you that you subjected me and my family
to a two-year period of grossly offensive remarks
about sheep-shagging, and then, when you were outed
by the suggestion that such behaviour meant that you
were unsuited to being a school teacher
that you made malicious, misleading and therefore
perjurous complaints to the plods that caused a great
deal of further distress to me and my family?

Is it not enough for you that one plod is now facing a
criminal prosecution for assault and that a further 54
complaints are outstanding against other plods as the
direct result of you inciting them with your lies?

Was this shameful behaviour insufficient for you that
you must now continue with your infantile jibes, with
your stated deliberate intention as quoted below?

There remains no doubt that because of your publicly-expressed
obsession with sheep-shagging that you are a danger to children
and that under no circumstances should you be employed as a
teacher of mathematics in Strood, Kent, or, indeed, in any other place.

For the last and final time, I invite you to publicly and
unconditionally retract and apologise for your scurrilous
remarks about sheep-shagging and your other remarks about
drinking methylated spirit. I urge you to do this whilst
you still have a free choice in the matter.

I will not ask you again, but if you do not retract and
apologise then I will seek redress from you by
means that are legal and decent, concepts that seem
to be quite alien to you.

I have that one, and I like it a lot, it is a very nice updated rewrite of Solid State Design by W7ZOI.

I could also call your attention to Jeff Carr's "Secrets to RF design", he pays a lot of attention to practical details not immediately obvious in theory. His read is actually a lot of fun.

Finally, there is a book I really want to read, "Voice of the Crystal", about the theory and practice of building RF circuits out of common household items and castoffs.

The Eternal Squire

So the person who appears to know everything about amateur radio, electronics and life in general, didn't know about such a good book?

If your employers had to recommend it, do you have a lack of knowledge somewhere?

Do they know the manner in which you post and contribute to this newsgroup? Do they also know your track record with the Well-Shite Constabulary? Your stance on Lillibet Windsor and Royalty? People in general? Partakers of the same hobby as you - 'ham'(sic!) radio - which supposedly encourages working together and collaboration - despite you detesting certain classes of the hobby instead of encouraging them to further themselves? I expect, especially if your employers are Japanese, they encourage working together and the value of fellow man?

Also, if your employers are Japanese, surely you must have some stance on working for those you detest - murders, warmongers and out and out torturers in the past?

Double standards Gareth deary.....tut tut....

Is the value of a capacitor placed in series with the secondary of a transformer multiplied (as viewed from the primary) by the turns ratio or the square of the turns ratio?

Thanks,

T

4322. Re: transformer basic question

Source record: 17055

If the transformer has a step-up turns ratio (from primary to secondary) then the resistance, inductive reactance and capacitive reactance connected to the secondary (as measured at the primary) decrease as the square of the turns ratio. Therefore effective capacitance measured at the primary increases as the square of the turns ratio. For a step-down transformer the effects are the opposite.

OK Bill,

I have a series tuned loop that is resonant with 1000 pf and fed into
a 10 to one step up transformer.

If I remove the 1000 pF cap completely, I can resonate the loop at the
same frequency with 10 pF in the secondary?

It almost sounds too good to be true:>:

Since the tranformer now becomes component of the tuned circuit, you would seriously decrease the Q of the tuned circuit when doing so.

Your original question suggested an ideal transformer, which the loop
antenna undoubtedly is not, therefore the detailed answer is more
complicated. The loop impedance is an LCR network that would require a more
detailed study, which I am not able to offer right now.

If your 1000 pF gets the job done, that is probably a good solution that
tunes out the net effective inductive reactance.

Thanks to both Bill and Harry.

I'm trying to vary the resonant frequency of a loop with an air variable. The loop impedance is under 1 ohm, so it needs a step up transformer anyway, and toroids are commonly used.

Since a 1000 pf varaible is much harder to get than a 10 pF, I was pleased to learn that I could multiply the effective value by multiplication of the actaul value times the square of the turns ratio.

It makes the job much easier, even if the Q of the loop suffers some.

Thanks to you both,

T

4329. VHF cavity resonator w/ regeneration as IF for HF RX ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-09-19 11:06:28 UTC
From: SpamHog <n1jpr@hotmail.com>
Message-ID: <1127127988.908809.33310@g43g2000cwa.googlegroups.com>
Source record: 17061

Resonant cavities have such good selectivity that are routinely used to consolidate antennas for concurrent use with multiple transceivers on same-band frequencies.

One can take a few interesting shortcuts to making them, both for ham radio
(http://web.telia.com/~u85920178/use/cavity.htm)
and professional installation (e.g.
http://www.raeng.org.uk/news/publications/ingenia/issue18/David.pdf
= http://tinyurl.com/cenqb - Not a joke, you can really use beer barrels!).

Does anyone have experience in using positive feedback to turn, say, a VHF fixed-frequency resonator into a regenerative IF filter for HF use?

Expected pros
- no images even with a modest front end low-pass filter
- single peak bandpass
- solid floor, possibly with ferocious immunity from strong nearby signals
- may provide direct detection
- for isofrequency transceive operation, a PLL or huff-puff oscillator could be converted back to receive frequency with good spectral purity with little filtering

Expected cons:
- possible thermal frequency instability
- tricky to feed to and pick up from properly, compounded by having to provide path for regeneration

Frequency would be rather unimportant, all tuning would happen in the local oscillator.

Did anyone ever try that? In particular, I am curious about the following:

1) Better a 1/4-wave resonator referred to ground or a ground-insulated loop? (The latter may be easier to fith with multiple mutually decoupled I/Os referred to ground).

2) Better single I/O or perhaps one each for signal path and regen amp? (The former easier to fit on a standard 1/4 lambda resonator worked against ground. Also, this could be done with a preexisting surplus resonator.)

3a) Suggestions for ready made metal containers - such as coffee cans, compressed gas canisters, large movie-type film spool cases, or

gold-flashed gas-inflated caramelized yak rumens?

3b) Is silver flashing a good idea, on either resonator or all over the inside of a cavity

3c) Or, what ready made surplus cavity would you suggest?

Greetings:

We recently acquired materials from the estate of Roger A. Jacobsen, K9KLN, which included a nice Quad 837 tube linear for 80m -> 20m(?). Please look at this amp at:

http://ipx1.cybertheque.net/ham/837_linear/

I would appreciate any recollections about the design, chassis layout, performance and similarities to other 807/1625 grounded-grid designs.

Regards,

Michael Grigoni

As mentioned on the website, the linear is basicly the same as one that
appeared in the 1957 handbook and in early ARRL SSB manuals.
That version used modified 1625 tubes, the 837 is very similar to the
modified 1625 but with lower plate input ratings.

4335. Problem of nearby transmitter breakthrough

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-09-19 22:07:25 UTC
From: Bob Chilcoat <viewptmd@optonlineREMOVE.net>
Message-ID: <wEGXe.4566$H24.1943@fe11.lga>
Source record: 17065
Cross-posted to: rec.radio.shortwave,rec.radio.amateur,rec.radio.amateur.homebrew

Sorry for the crossposting, but I'm looking for more expertise than I have. I usually hang out in the aviation groups, but am an engineer by training. I have a radio problem:

I have just completed a special rig for our local airport, but it has a problem. I took a rather old but serviceable Sony digital air band receiver (Air 8), boxed it up in a waterproof enclosure and piped the audio out to an FM microwatt transmitter. The idea of this is that visitors to our airport who like to sit in the parking lot and watch the airplanes can listen on their car radios on FM 88.1 to the radio traffic on our Common Traffic Advisory Frequency (CTAF), which at our airport is 123.00 MHz (AM). Unfortunately, while this setup worked perfectly at home well away from the airport, we have an Automatic Weather Observation Station (AWOS) transmitting continuously on 120.60 MHz only 50-60 feet from the place I need to site the receiver. Even though this is only a 5 Watt transmitter, it overloads the front end of the receiver. As soon as anyone keys on 123.00 and the automatic squelch is triggered, all you hear is the AWOS recording.

I've tried quick fix by attenuating the input signal by trimming (shortening) the antenna, but this doesn't really help. This was supposed to be a quick and dirty (gratis) job for the airport, and I've already spent more time and money on it than I wanted to. Any suggestions as to how I might fix this problem? Cheaply? Obviously a better receiver would work (my Yaesu aviation handheld works perfectly at the same location), but I have no other (free) receivers handy. I can move the receiver another 50 feet down the fence, which is my next option, but what if this doesn't work? I can't get it any farther away for several reasons. Anyone have a 120 MHz preselector they can give me? Any really steep (and cheap) 120.6 notch filter designs?

Thanks for any help you can offer.

Are you absolutely sure the offending signal is coming in via the
antenna? Is it there if you disconnect the antenna or replace it with a
dummy load (termination)? That strongly influences what you need to do
to fix it.

Put a tee connector on the receive line coax a length of coax on it with
a short at the far end. It must be cut to be exactly 1/4 wavelength
(including connector spur.) This will appear t be an open circuit at
the resonant frequency, but will severely attenuate your nearby unwanted
signal.

Failing that, a series LC network across the receive line will do a
similar task. Try a 47pf trimmer cap in series with a coil made from 4
to 6 turns around a bic pen. (you can remove the pen after making the
coil... :) Tune your receiver to the unwanted signal and tune the
trimmer until you see the unwanted signal drop out. You may have to
experiment with the coil turns and spacing, but this design will also
help wipe out the unwanted station.

Fortunately your undesired signal is likely a constant-on transmission
so it's always there for you to play with. Secondly, you can make and
tinker with all this at home (provided you live within receiving range
of the airport AWOS) and bring the working product to the airport for
installation.

Good luck.

B.

the resonant frequency, but will severely attenuate your nearby unwanted
signal.

Failing that, a series LC network across the receive line will do a
similar task. Try a 47pf trimmer cap in series with a coil made from 4
to 6 turns around a bic pen. (you can remove the pen after making the
coil... :) Tune your receiver to the unwanted signal and tune the
trimmer until you see the unwanted signal drop out. You may have to
experiment with the coil turns and spacing, but this design will also
help wipe out the unwanted station.

Fortunately your undesired signal is likely a constant-on transmission
so it's always there for you to play with. Secondly, you can make and
tinker with all this at home (provided you live within receiving range
of the airport AWOS) and bring the working product to the airport for
installation.

Good luck.

>Joe
>W3JDR

It has to do with where the spurs end up. If you are close to Fref/2,
lots of the spurs alias down to base band. Worst case is Fref/3. With
the proper choice of filters, and band choice you can find areas where
spurs are almost non-existent. If you have a narrow band application,
your frequency planning can find those holes. Make sure you have your
peak detector turned on.

There are lots of sources of spurs-- phase truncation, amplitude
truncation, noise, etc.

I am making some assumtions here. You state that you only hear the AWOS
when a transmission occurs on the CTAF freq. I would think this means that
the receiver is NOT receiving the AWOS signal all the time or it would
trigger
the system constantly. If you listen to the receiver output while at the
airport
does it contain the AWOS audio or just the CTAF audio? My inclination is
that the AWOS sig is being picked up by the interface circuitry between
your receiver and the 88.1 transmitter. If this is the case then more
bypassing
and rf filtering is needed on the interface. Then again I could be barking
up the
wrong tree here, only some suggestions, hope it helps.

Cheers

While this approach looks good on paper, it often fails badly when the
desired frequency is so close in to the notch frequency. I just put a
quarter wave stub on our VNA and found that while it does diminish the 123
signal -33dB, it also attenuates the 120.6 signal by a whopping -22dB.
There is also an enormous VSWR upset -120:1 or so- this is perhaps not
important in your receive only application.
Each year we build hundreds of filters for this exact application-
AWOS/UNICOM separation. Typical insertion loss is under 1dB while the notch
is >-40dB. The filter is about the size of a cigarette pack exclusive of the
N connectors.

ES:

My advice...

a) Start somewhere---with something. It doesn't matter what. Yes there is much to be said for planning and strategizing. On the other hand, too many people spend so much time thinking about doing things that they never actually do them.

b) The "perfect ham store" is the store YOU'd shop at if it existed. If you want to establish the perfect ham store, then create it according to your vision.

c) Whatever you do, make is scaleable. Running out plunking down thousands for shop space, equipment, advertising, and whatever is a risky proposition. Start with a single kit, a single service, a single piece of your own software, and market it on the web.

If it fails, your exposure was small and whatever money lost can be justified as tuition for the lessons you learned. Just try something else.

If it doesn't fail, you will have a small amount of capital with which to leverage the next product or service.

Bad thing to do and likely didn't reduce the signal as much as you'd
like. Try an attenuator, enough to kill the offending signal. Once
that is known the next step may be easier.

IF the attenuation needed is under 10DB and leving it in is acceptable
your done. Usually local signals are plenty strong enough.

If you need more than 10DB. Try a suckout stub tuned to the awos
at 120.6 as others have suggested. That should be enough as your
listening on 123.

>(my Yaesu aviation handheld works perfectly at the same location), but I
>have no other (free) receivers handy. I can move the receiver another 50

I'd try that first, distance will always help the problem. Allowing
for a plastic case on the RX distance is more liklely helpful than
filtering. The problem is the case of the RX is plastic and there is
no shielding so any filter will be compromized by back door entry.
A metalic water proof box with filtered ins and outs for RX and fm TX
will be needed then.

It's possible to make a filter with a steep enough curve for that by
using a bandpass section for 123 and a notch section at 120.6 using
sections of UT141 (.141" copper jacket coax).

I think you get narrower selectivity if you use an odd integer
multiple of quarter wavelengths for the stub. The longer the line,
the greater the phase change with frequency. A 1/4 wave shorted stub
goes from open to short in a 1:2 frequency ratio. A 3/4 wavelength
stub goes from open to short in 3:4 ratio of frequency. Etc. I think.

The receiver is already in a (steel) waterproof box. Tomorrow I will try moving the receiver as far away as I can. If that doesn't fix the problem, I'll try the stub antenna notch filter solution. I have a BNC Tee. Can anyone point me to the 1/4 wave length formula for 120.6 MHz? Does 0.591 meters (23 5/16") sound right?

I'm pretty sure right now that the interference is coming in on the antenna. It's not enough to trip the squelch, but as soon as someone keys on 123 and trips the squelch, the AWOS is on the audio. OTOH, I guess that doesn't prove anything...

I suppose the wiring to the 88.1 MHz transmitter or its wiring could be picking up the 120.6, although all that wiring is shielded (one audio line with shield terminated at only one end, and one 3v power line with its shield as return). The transmitter itself is in an unshielded plastic box, but that's mounted flat against the bottom of a 10" ground plane for the transmitter antenna. The last possibility is the 6v power line going into the receiver box. It's not shielded and starts at a wall wart transformer/psu very near the AWOS xmitter. I could put a few turns through a ferrite toroid just outside the box, I suppose. Couldn't hurt. Gotta find a suitable torroid.

Allison, I'm not experienced enough at this stuff to visualize how to make a bandpass section out of coax. I can follow the stub notch filter, but the bandpass isn't there. Could you explain a bit more?

Thanks to you all for all the help.

What is intermediate frequency (IF) of the receiver ? Some offending
signal (or mixing product) could fall on the image frequency and get
through that way.

Is the interface present when this transmitter is turned off and the
signal is monitored through the speaker ? If the transmitter cables
are disconnected, does this change anything ?

>to the radio traffic on our Common Traffic
>Advisory Frequency (CTAF), which at our airport is 123.00 MHz (AM).

One thing to try is to rotate the antenna, so that the receiver
antenna is in opposite polarisation than the transmitter position, one
in vertical polarisation, the other horizontal polarisation. This will
attenuate the offending signal by 10-20 dB. The null might be quite
narrow, so you would have to slowly rotate your receiver antenna to
find it.

>As soon as anyone keys on
>123.00 and the automatic squelch is triggered, all you hear is the AWOS
>recording.

If you defeat the squelch, do you constantly hear the AWOS
transmission ? Does it matter if the 88.1 MHz FM transmitter is on or
not ?

Any other VHF transmitters on site (VOR?) that might take part in the mixing process ? Do you hear any other background noises than the AWOS recording ?

> Does 0.591 meters (23 5/16") sound right?
==========

For the stub to work properly at the intended (notched) frequency , you must take into account the velocity factor of the coax. For a number of common coax types the velocity factor is about 0.67

For a freq of 120.6 MHz a quarter wavelength is 0.62 metres, so with coax having the above velocity factor the physical length is 0.62 * 0.67 equals 0.42 metres equals 16.4 inches.
However ,as mentioned before in this thread you could use odd multiples of this length

When you really want the stub 'as meant for the job' try to find someone with a spectrum analyser (with tracking generator) , cut the coax a bit longer than its calculated length and snip tiny bits off until the spectrum analyser shows the notch at 120.6 MHz.

On a different but related topic ; interference to a UHF TV sig by a nearby 144 MHz tx sig , I made a high pass filter and a downstream quarter wave stub which was subsequently optimised with the aid of a spectrum analyser. As expected there was also a clear notch at 432 MHz ,since the stub is a 3 quarter (odd)wavelength for that frequency. BTW the actual notch was at 144.4xx MHz being the part of the 2m band used for SSB operation in the UK , with SSB (varying RF amplitude) being a 'high risk' mode for interference. This HP filter/stub combination now permits the relevant radio amateur to operate on 2 metres ,be it with moderate power.

Wavelength is 300/F in meters. One quarter wave is 75/f in meters.
However your using coax cable and the speed of light (nominally 300 in
the examples cited) is slower depending on the coax used. for foam
types it's about .8 (varies by brand) and for solid types usually
around .66 (still varies some).

So for 120.6 a 1/4 wave section is 75/120.6=.62189M (24.4838").
A section of RG58 (solid dialetric) would be .66 that length or .4104M
(16.159").

To give you an idea of how critical that length is the 1/4Wave of the
same coax for 123mhz is .4024M (15.84").

So even small variations in VF (velocity factor for the coax) or
gutting error can make for big mistuning.

Generally speaking simple stubs work best if the two frequencies
are widely seperated such as 2m band and pagers at 153mhz
(5mhz minimum seperation).

>I'm pretty sure right now that the interference is coming in on the antenna.

Sounds like intermod. The front end of the reciever is being grossly
overloaded.

The average airband radio the difference of 120.6 and 123mhz is so
small to the front end that overload is common.

>I suppose the wiring to the 88.1 MHz transmitter or its wiring could be

>find a suitable torroid.

RF will com into the box anyway it can. Via power, antenna, audio and
even a poor connection between the cover and the box.

FYI: I'd bet anything that a few hundred feet of seperation from the
AWOS cures it or substantually improves it.

>Allison, I'm not experienced enough at this stuff to visualize how to make a
>bandpass section out of coax. I can follow the stub notch filter, but the
>bandpass isn't there. Could you explain a bit more?

If I had a way to post a schematic It would help. Suffice to say its
something that you'd need hardware to tune. The idea is that using
coax sections it's possible to get the equivelent of high Q tuned
circuits and couple them loosely for selectivity. Basically a open
ended 1/4 wave section of coax is a similar to a tuned cavity save for
a cavity at 123mhz is nearly 25" tall making coax less bulky.

So using an open stub creates a notch at some frequency, a shorted
stub is a tuned (resonant) pass at the same given the same length.
Visualize a feed from antenna, T with shorted stub(for 123), a 1/4
wave section for 120.6 section, another T with a open stub for 120.6.

Thats the starting point and it may be adaquate at that. However
to really make it work there is more and It's hard for me to describe
here. Sufficient to say VHF filters with that kind of selectivity are
not trivial to design and build.

Also obvious you need some instrumentation to tune the beast
for best results. Which is why there are people that build custom
filters for tasks like this.

The 1/4 wave stub works because of huge impedence upset it
introduces. However having a short (or nearly so) on the coax for
transmitting would be deadly for transmitters.

The problem is sections of coax have only moderate Q as resonators
and they are also resonant at harmonics.

I'd approach the problem by pulling the RF amp out of the radio and
loosely coupling to the mixer. Even a RX with 15uV sensitivity is
adequate for miles around an airport.

years ago, many cable pay-tv signals were scrambled simply with an
interfering carrier inserted at 2.25 MHz above the video carrier. The
'decoder' was simply a notch trap that removed the carrier.
It was quite easy to remove this 'scrambling carrier' with a stub of
coax, twinlead or even zip cord. Once you know the approximate length
its a matter of just trimming away in 1/4" intervals. I forget if the
qurater-wave stub remained open and the half-wave stub was shorted, or
vice versa, but you get the drift...it only takes a few minutes to try.
That said, its easy to do sitting on the floor behind the tv with a
steady signal but if you are trying to trap an intermittent signal in
the field it might be rather maddening without a test oscillator and a
means of measuring the signal. Then its placement into the 'system' of
iffy impedance may cause it to shift slightly.

IF you could find an old cable TV "Channel A" or "Channel 14" positive
trap it would be a cinch to retune it. I don't think any of the
commercial vendors would sell them as one-off, though...they only cost

about $6 new. Maybe somebody has one in a junquebox?

-Bill- I'm surprised my junkbox didn't yield one :)

Rather than building a trap, why not use a narrow bandpass filter?
Also, if you are that close to both transmitters, try attenuating the
signal from the antenna to prevent overloading the receiver.

One other idea. if the signal is from a transmitter at the airport,
why not see if you can take the audio feed to that transmitter and feed

the FM transmitter.

Source record: 17088

Additional cons:
- Increased noise from the regeneration
- Potential for distortion introducted by the regeneration
- Non-flattopped response because of the single resonator
(so you need to make the resonance broad enough that
you can do a decent job with another filter, likely at a lower
frequency)
- To get high Q with reasonable regeneration still requires a
BIG resonator (at VHF). High regeneration is difficult to
make stable.

I'd enjoy reading about the results of your experiments with this, but
I honestly don't have high expectations for its being practical.

A long time ago, I worked on a receiver that applied gated regeneration
to the energy introduced into a cavity by an antenna, up in the several
GHz region, and it was a sensitive design for a very specific purpose
that worked well with few parts. But that design was optimized to
accomplish a special task, and the design approach was appropriate for
that task.

Cheers,
Tom

The technical solutions, so far presented, are about as good as
you're going to get while still keeping the cost reasonable. However,
you ARE dealing with a consumer grade radio that was simply not designed
to any particular standard of interference rejection. And that you've
packaged this with a transmitter operating within the FM band also
offers the potential for overload artifacts on a broad spectrum of
frequencies. Sony Air 8, however, was known to experience this kind of
problem even off-airport. It would even pass 11 meter CB on a good day

if the signal was close, or large enough. As did some Sony FM broadcast rigs of the period when an aircraft was reasonably nearby.

I lived 2 miles off the approach end of 30L/30R at Lambert, St Louis for years, and I'd get aircraft to tower chatter on my Sony portable at 103.3, 102.5, even 93.7 everytime an aircraft went overhead. The front end was simply not robust enough to withstand a close-in assault of any magnitude. Nor was the chassis shielded well enough to prevent leakage through the IF's. Your real option may to select a different receiver. If you're doing this as a favor to the airport, you may get a decommissioned rig culled from a wrecked aircraft, or one that's been sitting on the shelf at one of the FBO's, donated to the cause. In that case, robust interference rejection is assured for your purpose.

There is, however another, and potentially greater issue at play here.

Rebroadcast of non broadcast radio frequencies may be in violation of several communications acts. Brush up on your regs, and be sure you're in compliance. In today's climate, there is always some asshat who has to make trouble for his jollies bringing the letter of the law down on fairly innocuous activities that may actually benefit someone.
And with overlapping laws written the way they are, today, you may be in compliance with one law, while in violation of another.

One of my colleagues, downstate, got a spanking for a similar type of service involving Air/Water show comms for a small airport near his home. Someone complained. Even though there was no interference was measured, and all hardware was in compliance for license free application. Unauthorized rebroadcast of comm channels was the issue.

So, make sure your ducks are in a row.

Years ago, I was in the last real radio store in Portland. They were on their last legs, and that's just what the owner told me -- people would come in, get demos of all the units, try them out, then go home and mail order one. I did, by the way, buy the radio he took so much time to demonstrate and explain. But the store was out of business shortly thereafter.

We get what we collectively deserve. You want low prices, you get low prices. Hello, Wal-Mart; goodbye, service. The modest success of EZNEC, however, does give me hope.

Without the manual you have no chance. In fact, even with it it's a challenge.... These sets have value, so if it's in good shape, sending it in and paying the bill is probably your best bet unless you are sure what you are doing.

It's common for MSS's to buy these just to have on the bench, for contract purposes, and actually use IFRs or HP's.

I bought a pile of books recently and among them was the Ed Romney "Fixing Up Nice Old Radios" book which you may be familiar with. For those not familiar he reprints the ARRL Handbook two-tube regen set which uses plug in coils. There is choke coupling to the audio amp with a 750 Henry choke.

I suppose I could get Sowter or Jensen to wind one, but is there an off the shelf part that will sub for this unobtainable little bugger?

>
> Thanks,
>
> T

Since I just started playing with the LMS impedance bridge featured in this months QST (and the current QEX), I thought it would be interesting to try to answer this one by experiment.

I have an old audio matching transformer labeled to transform 20 ohms to 8 ohms, a 2.5 ratio. I took a 10 uF capacitor and measured it at 9 uF, with Z of 14.43/_ -85 degrees at a measurement frequency of 1225 Hz. Hooked it to the low resistance side of the transformer and the meter to the high side. The reading obtained was 1.99 uF or Z = 74.4/_ -62 degrees.

So I got a transformation ratio of 4.5 or 5 in terms of capacitance or impedance, instead of the expected 2.5.

Now, how far is the transformer from ideal? Measuring its high side inductance with the low side open, I get 10.1 mH. This is the magnetizing inductance of the transformer, which appears in parallel with the transformed capacitive reactance. In a transformer that approaches ideal, the inductance is large enough to have a very large reactance compared to the transformed load from the secondary. In this case it's only sort of negligible. The transformed capacitance of 9/2.5 uF = 3.6 uF has a reactance of -j36.1 ohms. The reactance of the transformer's magnetizing inductance is j77.7 ohms. Combining the two in parallel gives a resultant capacitive reactance of -j67.11. And this is equivalent to 1.94 uF at my measurement frequency. Not too far from the measured value of 1.99 uF. I did neglect leakage inductance, assuming that it would be pretty small for this type of transformer.

Another interesting point to note is that the unadorned capacitor had a phase angle of 85 degrees, but the transformed version showed 62 degrees. The equivalent loss resistance of the transformer decreased the quality a fair amount, as one would expect I guess.

So I guess the answer to your question is yes, it will be transformed just like a resistive load would be, providing the transformed capacitive reactance is fairly small with respect to the magnetizing reactance of the transformer.

I don't have that book but you can use the winding of an old audio interstage xfmr in most of the ckts where such a choke is called for. That will be in the 10-30 H range and should work just fine. I've had good luck even using the little 200mw $1.99 transistor interstage xfmrs from Mouser. Don't know how many henries they represent but compared to the coil+resistance in a set of old 1920s phones that served exactly the same function in similar ckts it seems roughly equivalent....on the order of 3-10 H wouldn't be atypical according to the measurements one fellow made.

The National SW-3 uses such a 750H choke and you can also find one of several hundred Henries in the old BC-221 freq meters.

The audio will be down only slightly using a smaller value but quite honestly I don't see why they used such high values.

Not "all" hams are like that. I for one am not. But, I DO have a friend who is "cheap" and it sometimes embarrasses me to be with him when he tries to deal. "I" try to meet the person's price - if in reason and if I do need the item. IF not in reason, then I shop around - which is my option to do. What I WON'T do - is embarass them or make a smart ass remark about their price - I'll merely walk away. The only time I've ever retorted to anyone selling something was when they tried to get "new" price out of it, stated it was brand new in the box - when my eyes spotted a "modification" which wasn't done by the factory - and called them on it. Liars piss me off.

Source record: 16998

In my collection of crimp tools I have an Aim tool with a die for RG-58 BNC connectors, the new West Mountain Radio tool with a die for PowerPole connectors and a Tool Aid set with 5 dies for various insulated and uninsulated terminals. I've noticed that the dies for these tools all look somewhat alike with respect to the way they are mounted to their frames. The dies look as if they would fit all three frames.

If the mounting method and dimensions are the same, is there any reason not to use a die with a different frame?

Does anyone know of a cross reference of commonly available crimp tools that lists which dies are interchangeable with which frames?

Fred:

As long as you can determine the closure distance is the same, and the geometry is the same (primarily the way the crimp tool handles the pivot for the jaws), you should be ok. However, if the mounting is only "similar" be very careful of the two things:
1) the width of the crimp tool in regard to the slot in the die. If the slot in the die isn't the same width, it could be mis-registered and cause problems closing.
2) (and most important) be particularly careful that the closure is the same as the original crimp tool. Even a few thousandths of an inch makes a tremendous difference in whether a crimp is performed correctly, too loose (the dies do not close fully and the connection is not crimped with sufficient pressure to make the proper contact) or too tight (the die over-travels relative to the intended distance, which could damage the conductor or terminal used, even to the point where the termination is significantly weaker than intended).

Some crimp tools are adjustable to account for potential wear, and I've seen many a crimped connection that failed from improper setting of the tool, either too loose, which typically causes the joint to fail due to heat, etc., or too tight, which typically over crushes the conductor, making the termination break off at the shoulder of the crimp, or actually fracture the terminal material, causing it to fail and drop off under physical stress. Either way, the connection failed and caused problems later on. This is a particularly bad problem if the crimp is covered with heat shrink, as it "looks ok" until you put it under stress, either electrical or physical...

Good Luck

Hmmm, all very interesting...

K7ITM wrote:

> Additional cons:
> - Increased noise from the regeneration

As in all regens, it comes with the territory!

> - Potential for distortion introducted by the regeneration

Which may be also a plus, if detection is to be accomplished in the same stage. In normal concentrated-LC circuits up to HF or low VHF rejection of signals at f/2, f/3 (which could be picked up and amplified as a harmonics at f) tends to be good enough. This always looked a bit counterintuitive to me, but it works. In cavities I think one can also expect spurious resonances - no idea if regeneration makes the whole contraption lock on the main resonance (that of the resonator at fundamental) and kill all spurs.

> - Non-flattopped response because of the single resonator

I wouldn't be too surprised if it turned out to be too tight for voice (I can't do the math w/o a lot of additional learning though, any help is welcome) but it would still be OK for CW. Regens are used for SSB as well, and LCs have been used for ultimate selectivity until recently (see Drake R8), but clearly curvy is a distant second best to flat.

> - To get high Q with reasonable regeneration still requires a
> BIG resonator (at VHF).

YESSS! The resonators I've seen were rather thick brass stubs, and even w/o regeneration could kill off a transmitter signal off frequency by <10%. As a first step I'd play with a ground-insulated loop made with either a ~ 0.5-1 in. wide strip or pipe. I/O with coax-fed links worked off ground, and a 50 ohm broadband amp as regen. I feel mired in my deep ignorance - as in antennas, what should be avoided to avoid broad resonances?

> High regeneration is difficult to make stable.

This would definitely be a hands-on radio, like any regen.

> A long time ago, I worked on a receiver that applied gated regeneration to the energy introduced into a cavity
> by an antenna,
> But that design was optimized to accomplish a special task,

By any wild chance was it an ECM? I remember that such a solution was used in radar jamming. Cavity was powered, kept right below oscillation. Pulse comes in, big punch goes out on the same frequency. (You don't have to answer this one! ;-)).

Or was it a self-activating oven klystron for genetically engineered microwave-emitting poultry?

Source record: 17004

Does anyone know where I could get details for making the following items. The problem with books I have and ideas on the web are they seem to require much higher power levels and work at lower frequencies.

I typically want to test antennas and other equipment at 434MHz and 915MHz with power levels of 20mW.

1. Some sort of high impedance preamp to put in front of a Frequency counter and probe RF circuits.
2. High impedance RF millivolt meter
3. SWR meter for forward and reverse readings.
4. Directional coupler.
5. Sinad Meter

Thanks in advance for any info.

Regards

David

Rather than re-broadcasting the signal why not try something simpler.
Just set up an Airport Traffic room within the airport and pipe the
audio in. Hang some old pictures and other memorabilia of the airport
on the walls to make it interesting.

I'm not so sure that "Motorola" is doing tech support on that era of
equipment anymore. There are a few places - very few - that do offer Service
Monitor repair and recalibration. One such place is Cardinal Electronics
Inc. WWW.CARDINALELEC.COM
Another is NS Electronics Service, Inc. WWW.NSELECTRONICS.COM

I can't speak for either except to say I bought one that was just calibrated
a week or two prior to my purchase - by Cardinal. It seems to be ok!

If you have a directional coupler, you are most of the way to an SWR meter...

Especially if you are willing to make directional couplers for specific narrow bands (say 10% or 20% bandwidth), it's pretty easy to do. If you get the freeware "RFSim99" software, you'll find in it a tool to design several different types of couplers. One thing they don't make clear is that the coupling for the microstrip and stripline versions is for a structure 1/4 wave long. The coupling decreases as the frequency goes up or down from that length. It's certainly useable at half the design frequency, and in fact you can find articles on the web about how the coupling varies with frequency, and for structures that give broader bandwidth. If you only care about ratios (e.g. for SWR calculation), then the exact coupling doesn't matter anyway. For your application, at only 20mW, you'll want fairly high coupling. 20dB coupling would give you 100mV out to a 50 ohm load, for 20mW in.

I've seen articles in "Wireless World" for amplified RF probes. But a simple diode detector probe feeding a high impedance voltmeter will be a high impedance load to the circuit you are probing, so long as the diode has low capacitance. You should be able to find Schottky diodes that have 0.5pF capacitance at very low junction reverse voltage, I think, though they are likely to be pretty delicate. (Don't zap them with static!) With a high-resolution DVM to monitor the output, or with a DC preamp that has high input impedance and extremely low input offset voltage (such as the Harris chopper-stabilized CMOS part), you can see RF voltages down to below a millivolt fairly easily. You need to calibrate the amplitude response, however, and it drifts some with temperature. With a buffer amplifier, you could use one of the RF power monitor ICs from vendors like Analog Devices or Linear Technology and have more stable calibration, reading "linearly in dB". An advantage of diode detection is that it's very cheap, and you can afford to put detectors on your directional coupler outputs and just leave them there--plus they don't require power supplies. That 20dB coupler with diode detectors and high resolution metering would allow you to still "see" the reverse-port coupled power down 40dB below 20mW input with good diode detectors, and it's very unlikely you'll be able to make the coupler with such good directionality anyway.

If you don't already have them, you should add "step attenuators" to your list of equipment. It can be useful for a lot of things. You may be able to pick up a pair of 1dB step and 10dB step attenuators from some place like ebay, maybe even at a reasonable price.

Are you going to be making so many measurements that you need a SINAD meter?? Do you have an RF generator with calibrated output?

Lessee...20mW at 50 ohms is just about 1 Vrms. For that much power, you need sensitive amplifiers and high impedances?? If you really do need that for probing, you'll need an amplifier at the probe tip. 1pF at 1GHz is about 160 ohms reactance. But for that very reason, 1GHz circuits are designed at low impedances, and you shouldn't need a particularly high impedance to probe for frequencies, at least.

Cheers,
Tom

4376. Re: VHF cavity resonator w/ regeneration as IF for HF RX ?

Just a couple of thoughts in reply--I'm more interested in getting you to go try the thing and let us know how it works for you! Though I see problems with it and would personally go other directions, I can see it could be quite a bit of fun to play with if you're interested in it.

So, the Q of a 1/4 wave coaxial resonator (and as it turns out, also 1/2 wave and 3/4 wave and...) built from smooth copper conductors, paying attention to making very good electrical contact especially where the current maxima are, and making the structure be about 77 ohms (D/d about 3.6) should allow an unloaded Q of about 107*D*sqrt(f), where D is outer conductor inside diameter in inches and f is the frequency in MHz. So a 6" diameter copper tube with a "1.5-inch" copper pipe center conductor, at 100MHz, should give you a Qu of 6000, roughly. That would be a bandwidth (unloaded) of 1/60th of a MHz, or about 16kHz. Maybe that will help a bit. In general, for moderate to high Q, bandwidth to 3dB points is equal to center frequency divided by Q. But that's loaded Q, which will be less than unloaded. Of course, your regeneration raises the effective Q--it is after all a Q multiplier.

Oh, and don't bother trying to silver-plate the resonator. You're better off just making sure it's smooth, high conductivity copper (probably NOT that hard copper water pipe I mentioned above!) with very good contact everywhere, protected with a thin coating of clear acrylic lacquer to keep it from tarnishing. There have been controlled expreiments about silver plating that show it actually can make things worse, unless you get all the plating parameters just right.

The regenerative cavity thing was/is a receiver for pulsed radar, where the time of the return pulse is known, roughly, and tracked, so the regeneration is gated on at the expected time of the return pulse.

Cheers,
Tom

What I figured I'd do is just tap off a small practice guitar
amplifier for B+ and heater power (it's a homebrew with excess to
spare) and use it for audio too. So I shouldn't need too much audio
output.

The other question I have is, what relatively common miniature tubes
would be good to sub for the 5 and 6 pin ones in this circuit?

Hi,
Ive been trying to locate a suitable unity gain buffer amplifier IC that can drive a 50 load.
Application is to buffer a VCO output at 5Mhz.
Needs to be 8pin DIP and operate on a single-ended supply.
I had found what I wanted in the CLC109, but cant seem to find a supplier.
Any suggestions greatly appreciated regarding type and supplier that is user friendly to international countries.

Tom,

Thanks for the information.

I'll take a look at the coupler design in RFsim99.

The RF voltage probe and amp are not for the output of the transmitter
they are for "looking" at oscillators. I have a frequency counter that
goes to 2.5GHz but need to buffer the oscillator so as not to load it
down while probing. For lower frequency projects (VHF), I have a Tek
300MHz scope but the probes interfere with the circuits when I try to
"see" the waveform of the oscillator.

Thanks.

An AD817 can deliver +-50 mA and has a gain bandwidth product of 50 MHz.
http://www.analog.com/UploadedFiles/Data_Sheets/289066266ad817.pdf
<4$ from Digikey.
Good for either a gain 1 buffer or a gain 2 with series 50 ohm
resistor, 50 ohm source.

Unless you source with 50 ohms (2x signal plus 50-ohm resistor),
and terminate with 50-ohms, the issue becomes how much cable
capacitance? Either the load looks resistive (100 ohms in the
former case) or capacitive.

Hi,

Some of you, hopefully many of you, may be aware of the existence of the "Amateur Radio Course" project which provides a number on-line and downloadable tutorials for the various UK amateur radio examinations.

Due to the sudden, unexpected and unexplained withdrawal of support by the company who up to now have very kindly hosted our web-site free of charge, and their even more unexpected failure to communicate with me regarding how we might transfer or redirect the URL which they registered for us but now will not let us use, our site is no longer available to the clubs and individuals who benefited from it.

Can you therefore help us and please publicise as widely as possible the following information.

The "Amateur Radio Course" which was located at www.ukradioamateur.org is now relocated at www.radioamateur.co.uk

There may be a number of functions that are not working due to the sudden move, but they will be fixed within the next few days.

It remains, as always, a non-profit making activity sponsored and supported entirely by the group of individuals who give up their time and resources free of charge to support and promote interest in the hobby.

I apologise for posting this message in so many newsgroups, but I need the new URL to be publicised as rapidly as possible.

Many thanks to you for your help, best wishes and 73's

Rick-

Thanks for the pointers. I suppose it is common sense, but I wouldn't
have thought about the jaw pivot arrangement making a difference.

Today I found an Ideal Industries "Crimp Master" tool with a die for cable
TV connectors, in a local store. That makes 4 tools for comparison.

Based on your comments, I found that the Tool Aid crimper and the Ideal
Crimp Master appear to have compatible dies. The Aim has a smaller die
slot width. The West Mountain Radio crimp tool for PowerPole connectors
has a similar size die, but the jaw arrangement is different from the
others.

I tried a couple of the Tool Aid dies in the Crimp Master frame and
produced similar crimps with similar pressure compared to using the Tool
Aid frame. My next step is to try interchanging dies with a different
tool a friend has. Between us, we hope to find what kinds of dies are
compatible with our frames.

Bob-

By now you have probably solved your problem. If not, someone else suggested that you insert attenuation in the Sony's antenna lead. I think that approach is most likely to produce the results you want.

If you were to replace the Sony's antenna with a dummy load, there may still be sufficient signal bleeding into the radio to make your system work. The interfering signal would also bleed into the radio, but at such a low level that the Sony's tuned circuits ought to be able to handle it.

If even this does not solve the interference, you may find the problem to be audio rectification inside the 88.1 equipment, perhaps in the oscillator stage!

Please keep us informed of what it takes to make it work.

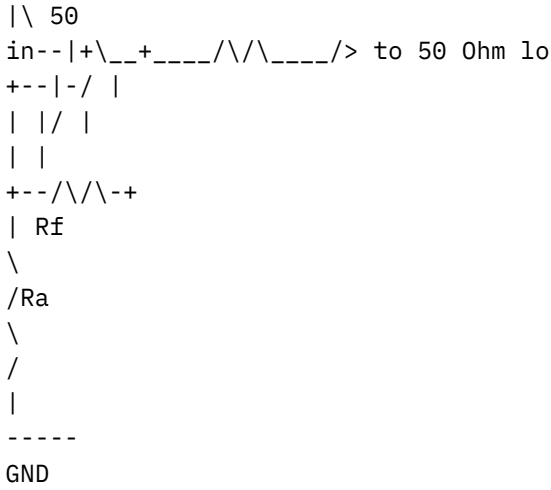
What you want is a video buffer or video op-amp. Linear Technologies,
National Semiconductor, and Analog Devices are among the many companies
that make such things.

Note that some of these devices get a bit squirrelly if they see a
capacitive load. So I recommend that you do something like this: (use
courier or other constant-width font for ASCII art schematic)



Rf and Ra would be the same value. Use a value recommended by the
datasheet, or 1k if the datasheet doesn't recommend a specific value.
Follow any other suggestions in the datasheet as well. For example, they
may suggest a small capacitor directly from the op-amp output to inverting
input.

You probably want to terminate the input with a 50 Ohm resistor, too, but
I don't know, so I'll leave it out.

It sounds like you may need AC-coupling, so you can put blocking capacitors on the input and/or output. Oh, if you put a blocking cap on the input, be sure to also provide a DC (resistive) path to GND or to the mid-rail point if you are going single-supply.

Just chose a capacitor big enough so that 1/(2*pi*R*C) is much lower than 5 MHz, your signal of interest. (R in this case is 50 Ohms) There is no problem putting a capacitor like this in the signal path: Since it looks like a short circuit at higher frequencies, it does not capacitively load the amp at frequencies where the amp might be unstable. Also, the series 50 Ohm resistor keeps the overall impedance resistive.

Why not just inductively couple to traces, assuming you have microstrip traces around that you can get to? Then you could use a common MMIC amplifier to get back up to a decent signal level. I'm thinking here of something essentially like the microstrip quadrature coupler I pointed you to, except the coupled line is in a probe, and is quite a bit shorter than a quarter wave. That just reduces the coupling. You adjust the coupling by how close you hold the probe to the trace you want to monitor. (The coupling really is a combination of inductive and capacitive, I guess.) I often probe with a tiny coil of wire at the end of a piece of coax, the other end of the coax terminated in a 50-ohm instrument (spectrum analyzer or scope). The coil might be two or three turns close-wound #32 AWG, a tenth of an inch in diameter. Just hold it close to traces that carry current and you'll pick up signal. (It's the cheap & simple version of the coupler idea.)

Cheers,
Tom

Thanks for those ideas. I was considering putting a low pass filter after
the amp. The 2 shunt caps work out to be 560pF each.

All,

Thanks for all the suggestions, advice and information. I learned a lot about VHF that I didn't know. Should have stayed with it way back when I almost finished my "Novice" amateur license (couldn't manage the Morse code part -- I guess that gives away my age).

Fred nailed it, although by the time I saw his note, I'd solved the problem. After relocating the receiver as far away as I could (60 feet, given the limitation of where the units needed to be and sources of power) which didn't really help, I tried some simple filters, etc. During the course of this, someone keyed a mike while I had the antenna disconnected, and it worked fine with no antenna connected! A bit more experimentation indicated that the 120.6 interference dropped out completely while the desired 123 signal could still be picked up from five miles away if I left the short coax jumper inside the box from the receiver to the antenna disconnected at the antenna end. I'm not sure I fully understand why I still get a pretty robust signal this way, but I guess enough 123 MHz RF is leaking in from the bare antenna or all the other wiring. Since the radio traffic of interest is mostly local planes near the airport or in the traffic pattern, a five mile radius is probably more than adequate, and this is certainly the cheapest solution.

I will also look into the regulations about rebroadcasting non-commercial radio signals. The transmitter satisfies the part 15(IIRC?) FCC reg about a 100-foot reception limit, but I thought the rules about rebroadcasting were to prevent <commercial> rebroadcasting. The 100 foot limitation will keep all reception on the airport grounds, but I will do some more research on this. Thanks.

As far as an area inside the building where people can listen to the radio is concerned, we already have that. This project is for the people who sit in their cars in the parking lot and watch the planes on their lunch hour, etc. We get quite a few of these. Anything that improves relations with the general public should help alleviate some of the problems we have with the neighbors. I still can't understand how anyone can buy a house near an airport, and then feel that they have a right to complain about airplane noise. The airport has been there since 1946, but that's another issue.

Again, thanks for all the help.

My turn...

Lots of really good ideas here. Make sure it is the Sony antenna that is picking it up...

1- The stub-trap idea may work with some large number of odd-quarter waves. As you stack more odd multiples of quarter waves on (extend the shunt trap length), the dips get closer together and as a result the peak-to-null distance shrinks. A stub that is 21 quarter waves long has peaks and nulls very close together (you could calculate this). Of course the dips will be less deep due to cable loss. This may make it easier to get the desired "Pass / Null" response. You need to make sure the signal is getting into the antenna and not the receiver itself. The 2.4 Mc spacing is quite close.

NEW IDEA:
2- Try tuning it on the image (for your 123 Unicom frequency). You will probably need to do this away from the airport . You should hear the Unicom in two places on the dial spaced _TWICE_ the IF frequency away. These radios usually have pretty wide front ends There may be a schematic inside the radio to help determine this. If the IF is 0.455, the image is 0.910 away. This radio probably uses low side injection meaning the LO is below the 123 by 0.455. Therefore you must tune the radio 0.910 HIGHER than 123. This places the on channel further away from the 120.6 AWOS. Not knowing the IF, you have to hunt.
-Maybe doing this _AT_ the airport will yield a tuning that fixes it. Just try "tuning around".
Related idea, you could also figure out where the RF stage stuff is in the radio and de-tune it upward to get more attenuation at 120.6, but if that works, then just some attenuation in the antenna line may work as well and be easier.

3- Put the radio FAR away, but run the audio in some small coax to the 88.1 closer to the visitors.

4- I like the "cross Polarization" idea. Do a light saber thing with the Sony antenna. There may be a sweat spot that just might get the levels down and fix the IM or whatever is going on..

Mike T. Use the airport receiver...

Sounds good, but they probably don't want you messing with it.... and what about the airport's transmissions...

5- HOWEVER, how about simply a microphone right next to this receiver and within earshot of the airport's microphone---ON the 88.1 Tx ?? You may hear other stuff in the FBO, but it may be ok too...

Related... I have a little thing I plug into my dual band rig speaker output and it transmits the audio to my car FM radio. They're made for listening to battery operated CD players in your car.

Around here, most "lounges" or "Terminal buildings" are inside the
fence, so the original problem remains that limits non-pilots (or pilots
who happen to be driving by a strange airport) from gaining access to
the field.

Yes, indeed, but you are arguing against a brick
wall here - those who hold, or who have ever held,
a licence issued under the gangrenous degeneration
that is the M3/CB Fools' Licence scheme, especially
those who were either too lazy or too stupid, or both,
to be able to tackle and then pass an exam aimed
at 14-year-olds and had to go instead for an
exam aimed at 6-year-olds.......reading just isn't
their strong point!

Just a wild guess - power supply issues, bad connections? No screen - no voltage to the scope section. No change of mode - no voltage to unit controlling said functions. Not having a manual myself, this is all I can say with any degree of certainty. Myself, I have a 2001C.

Problem, PS is good (more or less) voltages are fine.
When turn it off then I can see some blink/flash on screen, thats all.
CPU unit ?
Why continious tone from speaker ?
Must be some error, but where ? :)

Well, without a manual of my own, I can't go any further..... Sorry!
Unless I get one, some day I too will be in the same boat.

Can anyone out there help with a slight problem? I have in my posession an AM-1180/GRC 100w FM amp, 50-100mhz. When i purchased it years ago it came with a schematic, which showed what voltages it needed where in order to operate. Anyone have experience with this type of unit? It uses a 4x150a power tube, and one hellacious roller inductor and capacitor.

I would either like to use it or sell it, but in either case i need a schematic.

You can still find junk AA5 radios in the trash from time to time and rip out their 455khz if cans. 85khz transformers from arc-5 radios are STILL out there at hamfests, and the bc453 radios they came from show up often on ebay. I think I have a few of these cans in my junk box. You can pad them down to 50khz if you want, but there is nothing wrong with the 85khz if frequency. The arc5 cans have a feature where the spacing between the primary and seconday windings is variable. Remove the top cap and pull up on the fiber rod to increase the spacing, push down on it to move the windings together. With the windings spaced out you get a nice sharp peaked bandwidth, with the windings together they are over-coupled and you get a bandwidth well suited for ssb phone,
A Q multiplier and/or t-notch filter both work well at this frequency.

Some of the ARC-5 85khz cans had tapped windings to get better Q by connecting the grid and plate of the tubes 'below' the high impedance end of the coils by a few percent. If you exchange the hot and cold ends of the coils, the taps might work out well for bipolar transistor impedance matching connections!

Using the built in frequency multiplier of the 9951 will increase your
phase noise, but so will driving the chip at a lower frequency. I've
been told that the built in multiplier also RAPIDLY increases the power
the chip pulls and the heat it generates, so given a choice between
doubling the frequency with the multiplier and living with 1/2 the
frequency drive, (especially if you already have a 200mhz source)
I'd not use the multiplier.

Hi,

As anyone a paper or electronic manual for the HP 1707B Hewlett Packard
Oscilloscope. I believe there is an A version, which I think would be
o.k.

Maybe know of a website where it can be downloaded, preferably for free

Will pay for any postage or materials if required.

Well, yes, your probably correct - I am sub literate. Should have been reading English textbooks instead of radio ones. But then, if I had, we wouldnt be having this discussion, because I wouldnt be interested in reading radio related posts as I would be fully occupied arguing about grammar. Just as pointless, really. And not germane to the original post. Gosh, this is exciting! - I DO enjoy talking with people who are clear, concise, and to the point.

4433. Re: solid state 6m amplifier/IRF 510!

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-09-29 02:04:34 UTC
From: WSQT <wsqtradio@ziplip.com>
Message-ID: <1127959474.884834.102440@g43g2000cwa.googlegroups.com>
Source record: 16966

We pirates have made the common, ordinary IRF 510 MOSFET work much higher than the 6M ham band-like at 88MHZ! For several months WSQT Guerilla Radio(The Squat in DC) was on 87.9 at 10W with a single IRF 510 as the final. Details are in an old post to alt.radio.pirate. We later went up to a dual 6146 tube final for more range, and are now relocating because FEMA didn't like our Katrina coverage and whined to the FCC ,who only seem to trouble us around things like Katrina or the Inauguration. Four months of 10W and 3 at 40-50W with no trouble, but 1 1/2 weeks of Katrina coverage and they came running! Well,we'll soon be back, but meanwhile I figured you guys would appreciate some design info. Never have I found any article on the IRF 510 at VHF, so I did all my own research.

Although I understand many hams don't like pirates, we read your newsgroups and manuals to learn how to build decent transmitters that don't pur out spurs and hash, and I figured maybe you guys would enjoy a return of the favor.

Anyway, I've gotten 13 watts from one IRF 510, with a little over 1 watt of drive. This is with tuned input and output circuits, not broadband. I've heard others have broadbanded these things that high, but I can't possibly see how with all that input C! I've never sen an article on how they did it, only a comment to my original research data and article an alt-reaido.pirate.

That 13 watts could in turn be used to apply greater drive to another 4 of these things either in parallel push-pull(possible oscillation problems but I've done this with the 2N2222 for a driver), or with resonant 3 winding combiner transformers. Estimated output: 60 watts if you get it right!

Given that I can make the IRF 510 operate at 88MHZ, it should operate at considerable greater efficiency and gain(better input Q and higher capacitive reactance)at 50-54 MHZ. What I want to know is this: can any of you guys one-up me and get at least 8W from one IRF 510 on 2 meters?

If we pirates can make this device operate at 87.9MHZ, surely one of you can get it to work at 144! Best thing about the IRF 510-it costs less than $2 and is available at any Radio Shack!

>later went up to a dual 6146 tube final for more range, and are now

>>>>>>>>snipped>>>>>>>>>>>>>>>>>>

Several questions. Operating mode? Class A, B, C, D, E?
Stage gain?

Answer makes a difference. SSB required at worst class B
and class C would cause way to much distortion. While FM
is typically class C as there are no amplitude variations. This
makes a great difference is operating characteristics and
power out.

Since SSB and most amateur uses are narrow band by nature
any spurious outputs are undesired. Amps using the IRF510 at
HF have been built but their purity (IMD and harmonics) is only
adaquate to barely so and tends to degrade as frequency is
increased.

FYI: to feed an IRF510 as broad band you need to match the
50ohm input to less than 2 ohms reactive at VHF. This is
hard to do for greater than octave frequency ranges as it
is all reactive.

With that I've run an IRF510 at 6m (50mhz) linear (class ab1)
with a stage gain of around 9db and with 24V around 4W.
It was difficult to match, unstable tending to oscillate, and
prone to thermal runaway (case has high termal resistance).

A scrap final from a CB (2SC1307) gave me 7W, clean at 12V
and far less stability and matching issues plus cleaner IMD.
For the same effort a MRF492 at 50mhz easily delivers
90w at 12V and 11db gain as linear. That same 2sc1307
class C will deliver 12w and would drive a MRF492 to
100w class C.

To put it bluntly, for the effort to get 10W out of a IRF510
I can do far better with a 22$ transistor and still be ahead.

Hi,

Was wondering if a wideband preamp might have a better noise figure if its input impedance is greater than the antenna's. It also has a couple of head to tail 1N4148 diodes across the input for protection. Would removing the diodes extend the bandwidth or is the extra 8 pF stray diode capacitance become lumped in with the coax capacitance? Surely the preamp input has some capacitance too, so how does this affect the voltage delivered? Please, answer at your convenience.

A*s*i*m*o*v

... Ok, I pulled the pin. Now what?.....Hey! Where are you all going?

Yes, but not with any significant power output and the gain would be
poor at high power. This is known as cascode configuration and is
used at low power (milliwatts) with good results.

What those diodes will do is make horrible intermod if you've got a transmitter anywhere nearby. Especially if it's wideband with no filtering on the input.

> Was wondering if a wideband preamp might have
> a better noise figure if its input impedance is greater than
> the antenna's.

Freaking around with impedance mismatches just to get a better noise figure will only work for marketroids. Has no benefit and only penalties in real life.

To quote H&H: "Big fallacy: don't try to improve things by adding a resistor in series with a signal source to reach a region of minimum NF. All you're doing is making the source noisier to make the amplifier look better!"

Most RF amps spec noise figure for Z_in = 50 ohms and don't even try marketroid stuff anymore.

Tim.

The diode capaitance is low and really not a factor in preamp gain or
noise. They are non conducting and the capacitance is easily absorbed
into fees and matching systems.

The exact match for any preamp to antenna is a complex as it depends
on device, circuit topology and frequency. Generally with most fets
the ideal transducer impedence for best gain and low noise is higher
than 50 ohms. For most bipolar transistors it's less than 50 ohms.
Getting a reasonable match and incurring low losses in that matching
network are challenges. Every DB of loss at the input contributes
negatively to system noise figure. This includes feedline [coax]
between the amplifier and the antenna.

With all that... Wide band amps generally are of the feedback type
and unless they are of the Norton topology they are noisy. Added to
that is wideband noise has more total power than a narrow band
segment of noise fro the same source. So it goes to say that narrow
band amplifiers generally have the lowest noise.

For HF this is rarely a real problem as most amps have low enough
noise to be useful as the environment is very noisy. As we
transistion to low VHF and higher this case changes greatly. It's
also at VHF and higher that low noise amplification starts to become
significant and more difficult to achieve. Modern high performance
devices however may make this appear simple. For example a wide
band mimic MAR-6 achieves 20db gain 3db noise figure to upper UHF.
However 3db is only ok, as a good Gasfet at 430mhz will be less than
.8db noise figure and even fair number of cheap bipolars can achive
sub 1db with ease.

So it's really an issue of what noise figure you really need and what
bandwidth you need it to cover. For ham purposes this is an issue

for practical consideration for 10m and above weak signal work or space comms such as EME. For serious weak signal work in the VHF/UHF realm you have to look at the antenna system and feed system as part of that noise figure.

4441. FM SCA adapter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-09-29 23:56:36 UTC
From: mcalhoun@ksu.edu
Message-ID: <dhhuvk$k95@unix1.cc.ksu.edu>
Source record: 16974

I've always wanted to build an SCA adapter for an FM radio so I could see what else is available in the 88-108 MHz band. A web-search found lots of schematics, but I'd appreciate suggestions as to which schematic YOU have built that works.

4442. Re: solid state 6m amplifier/IRF 510!

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-09-30 02:07:13 UTC
From: WSQT <wsqtradio@ziplip.com>
Message-ID: <1128046033.694176.232710@g14g2000cwa.googlegroups.com>
Source record: 16975

I run the IRF 510 essentially at the "class B threshold"(leakage idling current but nowhere near linear range), simply because I could not drive it hard enough to run it without bias like in the AM BC band transmitter(Oct 03-Jan 05). Envelope distortion is not a factor when frequency modulation is in use, of course. Stage gain with 1W drive and 10-13W out is essentially 10 db-not great, but I've seen a hell of a lot of RF transistors speced with gain from 10-13db.

If you want to use the IRF 510 for SSB, I have no idea what the IMD will be,but I've used them at audio as modulators for the old AM rig. If anything, your stage gain will be the same or greater. I used 3V bias, generating leakage current only in the FM rig. For good linearity at audio(and presumably for SSB as well), you need to bias them further forward than threshold(they are NOT like darlingtons at audio for this!), and you will get more heat. I've had them on the scope at audio with sine wave drive, and they needed to go well into AB1, so much so that they made measurabgly more heat than darlington bipolars did for an audio amp.

No way will they be MORE linear at RF than audio, so run them in AB1 if you want AM linear or SSB. CW or FM, just set the bias pot for maximum OUTPUT, and you will get about 3V when running in the VHF range, as turn-off time seems to lower output with more bias. As a result, they like to be "centered" between "on" and "off" for maximum efficiency, which still sucks at VHF.

I would not be entirely suprised if an IRF 510 amp proves a CW and FM only deal at 6M, and I would bet on it at 2!

On the other hand, efficiency at 6M will be better than at 3M, so you should be able to stay within acceptable dissipation, even if AB1 bias is CUTTING output with the same drive as "threshold B" bias. Shit-SSB's a low duty-cycle mode, while at FM the duty cycle is 100%! This should compensate for the extra heat of AB1 operation necessary to make the IRF 510 linear at ANY frequency, even audio.

When I used the IRF 510 in the AM band as a drain-modulated Class C pair, they could make 55W carrier but only sustain 35-40W carrier for 30 minutes operation. Years ago, there was a well-published design for a broadband HF aming this device, accepting as much as 80W pep at 40M!

Spurious outputs, BTW, are as undesired for what we do as they are for amateur work. If you get spurs and they bring the FCC, you can probably resolve the issue. For a pirate, spurs can cause mean MUCH more serious "difficulties!" I have a lot more trouble chasing them out of exciters than amps, but always check out both very carefully.

Voltage used in the FM rig is 30V, the AM rig was 17 volts B+, going
to 34 at 100% mod. With tuned input and output circuits stability is
excellent, and unlike multi-2N222 drivers I've never had to chase hash
or oscillation with the IRF 510. Of course, a big bulky heatsink
serves as a groundplane, with all parts screwed to it.

Glad to hear I'm not the only one to push the IRF 510 above 30MHZ!

Source record: 16976

Grounded gate? Not too likely with the IRF 510. You will need 5V drive at least, at all full current! Since a grounded gate(base, grid) amp has only voltage gain, you would have a theoretical gain of maybe 3db at 12V, 6db@24V, and so on,but given unity gain from the IRF 510 at 12V grounded source at VHF, maybe unity or worse real world at VHF regardless of supply voltage.

The IRF 510 has a maximum peak voltage of 100, thus a maximum safe supply of around 34. Of course, a tube with several hundred volts supply(or several KV for a big one) is quite another matter, as are those 1KV peak MOSFETS as seen in some Class E 160M/80M rigs. No idea what input C is in the latter, though.

Lastly, at grounded gate you still get the same voltage-variable 135pf gate-source C as your input C, you just get out of the Miller C, which is an estimated 22pf times 2 for an MF/HF rig with 12V supply and 12V drive, or times 3.5 for a 30V supply. Input loss gets damned high in this capacitance, and this is why a device that(grounded-source) at MF has 30dB gain has 10dB gain at VHF.

Cut to the chase. The only thing the IRF5xx series has going for it is it's dirt cheap. The problem is that coaxing them to deliver is more pain than better devices. Good devices in reasonable circuits have one advantage, repeatability of performance.

As to MW am service, I'd use the heavier devices and run them class E in the several hundred watts to KW range. Even the IRF510 in class E is good for more than 50W for a pair and should run reasonably cool. Even the really big E amps only need a few watts as excitation. This works because they are being used as switches, what they were designed to do. A class E amp can be "plate modulated" in the usual way but a PWM modulator will be far more efficient. There are a number of people running class E Am phone on 160, 75 and 40m and they sound very good.

For decent RF designs that withstand impossible swrs a good RF rated device is hard to beat. The real problem is finding a source that doesn't mark them up 500%. However there are some devices out there that are like the venerable 6146 they do the job and can be had at less than 0.40$/watt. For 6m the MRF492 for example rated power out at 12V of 70W and most deliver 80-90. For the price it's cheap.

For 2m I'd just grab a MRF247, easy 75watts at 2m class C or B and a pair with Wilkerson splitter/combiners deliver a heafty 145watts on the Bird. They work well for 2m SSB service with decent IMD. the last pair(matched) I bought as for a commercial amp repair only cost 70$. For that kind of power that's cheap.

I've built various 565-based units over the years. I only used the schematics I found as starting points; the main one I used to start from was the one included in the old, old 565 data sheets.

Make yours tunable, as SCA can range from 57 to 92 KHz and frequently a station will have three different carriers with different material on each. If I were doing one today, I'd use decent op amps as high-pass for the input side and low-pass for the audio output, instead of passive filtering. Especially at the output, I couldn't put in enough stages to de-hash the sound without losing what little high frequency output there is.

I might try a newer PLL as well. There was always something about the 565 that just seemed a little hinky and oversensitive to parameters. I was never entirely satisfied with what I got, though some of them worked pretty well considering all.

Don't be surprised if lots of what you find is digital signal.

I would say it depends on the cable you choose. If there is a 50 Ohm load
and you connect it to your buffer amplifier with 50 Ohm coaxial cable, then
the buffer amplifier will see a 50 Ohm resistive load, not capacitive at
all.

It is probably still wise to use the gain-of-two amplifier and 50 Ohm source
resistor in case the load happens to be a poor match. If you really don't
need this feature then I would be tempted to use an emitter follower with
just one transistor. (Do they make transistors in DIP-8 packages?)

Robin, G4DVJ, and Chris, G8LVK, have put up on their Monitor Internet website their hardware mod for the Realistic/Radio Shack DX-394 for downconversion to a 12kHz 3rd IF for DRM and other sound card DSP demodulators such as SDRadio. A beautiful piece of work it is, too, both in execution and publication, incorporating the Sat-Schneider module. That prompted me to look over the other mods and I see some added illustrations, if not additional mods, since I last looked. The bhi DSP module installation is especially sweet, albeit pricey.

So if you have not visited their site in a while, do so, and be inspired! Its at
http://www.monitor.co.uk/radio-mods/dx-394/dx-394.htm#mods

Great job, guys!

Are you referring to Anderson Power Products, specifically their
'MultiPole' line as shown here?

http://www.andersonpower.com/products/mp/mp.html

The connectors themselves can be had through Allied Electronics.
Take a look at this link.

http://www.alliedelec.com/Search/SearchResults.asp?
SearchQuery=Anderson+Power&Submit=find+it%21

Keep in mind, though, that you'll need a specialized (and
expensive -- $200 at least) heavy-gauge crimping tool to deal with the
heavy-gauge contacts. If you can't get hold of the appropriate tool
(Greenlee makes a very nice hex crimper -- it looks like a big pair of
garden shears, but with crimp dies instead of blades), I can offer
small-scale assembly services at a cheap rate ($40/hour, half-hour
minimum, see my web site, etc.)

Happy hunting.

And it is fund to build stuff. The old sig gens were pretty simple, with
most of the hard work on the dial. The Eico 320 was pretty popular and
you can use the manual to build one of your own:
http://www.nostalgiaair.org/References/Manuals/EIC/EIC_8.zip

But you can replace the triodes with fets, lower the voltage to 12 volts and
get the same results.

Steve.

A lot of the modern signal generator projects are based on the Analog Devices AD9850. Analog Devices actually encourages hams to use their sample service, so the part itself is no problem. It is relatively simple to program, so you may choose the microcontroller of your choice, although most of the projects out there seem to lean toward the PIC.

The challenge could well be the circuit board. The 9850 is only available in TSSOP so you need a good quality circuit board to attach it to. If your PCB skills are good this won't be a problem. But if not, you might need to hunat around for a protoboard or something of that ilk that you can get in your location. Unfortunately, these tend to be kind of pricey.

4460. solder paste for SMT?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-02 18:57:28 UTC
From: TRABEM <>
Message-ID: <b9b0k1pd7ham6i20iuvhqig67t7qnj9v8l@4ax.com>
Source record: 16993

I had some solder paste that was sent to my employer as a sample. The boss gave each one of us a tube, which was 10 CC of paste in a syringe. On DIP and through hole components, it worked great. But, it was worthless (other stronger words inserted here) beyond belief for SMT.

We use pyropens for rework, which is butane powered hot air. Except it has a twist, the hot air is passed through a catalyst, which consumes the oxygen. The lack of oxygen in the output of the hot air stream makes the solder job clean and wetting is very fast and easy because the part and the solder doesn't oxidize when the heat is applied. The lack of oxygen removes the need to preheat and lets the flux do it's job-there is really no need to preheat if you can get rid of the oxygen in the hot air stream, try it, you'll like it!

If someone would make an inexpensive dispenser for distributing the paste evenly, I think the paste would be viable for soldering and for rework. Without a means to dispense small quantities of paste on demand, the paste method is truly useless (IMHO).

In the end, we used the paste for soldering wires to some thermal switches we were building, a horrible waste of some perfectly good product! But, the company that made the paste wanted $450 for a fancy air dispenser, that should have cost $69. Our opinion was that the boss should save the money and we told him so. Since that time, we had 2 visits from sales people who tried to sell us paste. In each case, the paste was reasonably priced, but the applicator was worthless or cost 5 times what it should have!

We are doing alot more rework with SMT these days, so are still looking for a solder paste with a reasonably priced dispenser.

Does anyone know of a proper dispenser for solder paste, such as an air driven or a fine pitched thread to mechanically drive the syringe in small increments? Or, perhaps a small linear stepping motor can be used?

NO NO NO NO NO..............

LISTEN to TIM!!!!!!!!!!!!! Tim is correct, you are WRONG.

While the diodes might be benign in the presence of small and medium sized out of band signals, they do exactly what Tim said in the presence of large input signals like you might find near transmitters. Remember, the 200 KW FM broadcast station at the end of the block, or the 5 KW AM broadcast band transmitter down the road from you. Even though these signals are no where near the frequency you are trying to listen to, the diodes will see them and act as a non linearity and produce IMD all throughout the radio spectrum.

Remember, these diodes are not protected by a frequency selective tuned circuit.....so any big signal that comes down the antenna is gonna make a problem for you , especially if you're trying to listen to a weak signal.

Tim is correct.

Years ago I was working for a tv station as a chief engineer. I had to oversee the installation of the new 900 foot tower and make sure the tower monkeys aligned the dish properly for the STL. So, I spent quite a few days at the site. The guys putting up the antenna had just purchased new ICOM HT's and had them modified for out of band operation so they could use them for communication between the tower people and the ground crew running the wench.

I told them I had the same radio as they did, (which was true). When I showed them my radio, there were no odd audio sounds coming out of the speaker. When they turned on their radios, all they could hear was the overload from the FM station sharing the same tower.

The owner of the tower company was a ham and modified the ICOM's with back to back diodes at the antenna to keep the front ends from blowing out because they often worked within 10 or 20 feet of big powerful antennas. He told me without the diodes he added, he would lose one radio per day to rf overload and he used to carry spare front end transistors. Part of his evening ritual was to sit down and remove the blown front end transistors and replace them. He had done it so many times he could do it in 5 minutes! But, after he put the diodes in, the front end didn't blow anymore....but they always had interference from other transmitters as a result of the diode mod!

He learned the hard way not to introduce non linearities before the front end tuned circuits! I think you need the same lesson Allison.

I took one of his radios home that evening and modified it. I basically removed the gasfet front end transistor and threw his back to back diodes in the trash. I added a 10 db pad to attenuate the incoming signals across the entire spectrum. They spent about 3 weeks doing the tower job, and by the end of the job, I had modified all his radios. They never had another interference problem and they never lost a single front end. The owner was a good guy and offered to pay me dearly for tweaking his radios.

With all due respect, the diode capacitance is IS NOT the problem. It's the non linearities associated with the rectification in the presence of big out of band signals.

Listen to Tim, he's telling you the truth!

I put your tirade on the end of this as it's not relevant to the
orininal question.

First: the question, reread please. The question was a about
bandwidth of a wide band amp and noise figure. Overload performance
was NOT addressed. If it were the first thing would be to rid oneself
of those diodes. A good device will usually withstand more than the
diodes (U310 fet in common base amp I've used for Preamp took 25watts
before expiring as a test!).

However I do not need you lesson on that either. I design and build
both professionally and as a ham VHF op. My experience includes one
idiot that runs a KW onto a M2 7 element 800ft from me to work local
repeaters! On an average day I have between +10-20DBm of rf comming
fown the coax when hes operating. I know more than you suspect or
even checked about working in a RF rich environment, about 35years of
experience in landmobile plus commercial.

Now if you can address the question of amp bandwidth and noise figure
and diodes we can help this person. NOT drag the topic off into the
woods.

Further I happen to have posted at the same time as Tim and was not
contradicting him or addressing him. I was answering the author of
the thread.

Which is something I can't begin to understand. With the AVRs, you get
a faster chip with an industrial-strength C/C++ compiler that also
happens to be free (as in beer).

I guess some people are just really, really, REALLY into PIC assembly.
There's no other explanation for its popularity in the ham community.

> The challenge could well be the circuit board. The 9850 is only available

Actually the AD9850 comes in a SOIC package with 20 pins/inch, or half
the spacing of a normal DIP IC, rather than a TSSOP (0.5 mm lead pitch,
or about 50 pins/inch).

It is not hard to work with a SOIC dead-bug style. TSSOPs are a
different story; they really need to be mounted to a PC board,
especially if there are more than 16 pins to deal with.

4465. How to feed a long half-square?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-03 02:54:27 UTC
From: mcalhoun@ksu.edu
Message-ID: <dhq6h3$b6r@unix1.cc.ksu.edu>
Source record: 16898

I have room to erect a "half square" (aka upside-down phased verticals?)
20-meter antenna to be fed at one corner (low-impedance location; attach
50-ohm coax) or at the bottom (high-impedance; use a matching network):

```
A B
+--------------+ 1/2wave long
| /| 1/4wave high
| / |
/ Matching Network
Coax
```

Unfortunately, I do NOT (because my house is in the way) have room
to make it a more-balanced curtain:

```
A B C
+--------------+--------------+
| /| |
| / | |
/
coax
```

However, if I skip the middle "vertical", I have room for four vertical
sections in a space that should have five:

```
A B C D E
+--------------+--------------+--------------+--------------+
| | this part will be about | |
| | 10 feet above the peak | |
of my house
```

FWIW, line ABCDE will be about 30 feet above ground.

I've never done any antenna modeling, and I've never had any "feel" for
antenna phasing (EE degree notwithstanding), but I suspect feeding it
at the original corner (B) will result in somewhat unbalanced currents
almost everywhere.

QUESTION: Is there any not-too-difficult way to feed it at point C,
especially without a lot of cut-and-try (since a lot of
tree- and ladder-climbing will be involved)?

What about, for example, bringing x-wavelengths of coax BC and CD to a
common point somewhere above ground level (my shack is in the basement)
and connect them with a T to the coax that goes through the wall to
the rig? What lengths?

Thanks max,

I sure don't like the looks of that 100 dollar dispenser. It looks big
and heavy and not sure why it needs to be so large. I was hoping
someone had something small and cheap that would be nice and light.

The model 850 looks like it could pump grease into ball joint on cars!
I don't need or want anything heavy and over powered like that.

I don't see anything like that in the Digikey or the Mouser catalog.

Can you give me a model number or the manufacturer of the one you
bought 2 years ago? Does it work well for dispensing small amounts for
SMT sized PCB pads?

Thanks,

T

The original post (by A*s*i*m*o*v) mentioned back to back diodes as protection, so my reply was quite relevant.

Not sure what ruffled your feathers so badly Allison. But, whatever it was, I am sorry if I did something that didn't meet with your approval.

I also worked professionally as an avionics tech, and was in the business when the first Motorola commercial repeaters using synthesizers were put up...and they wondered why the other repeaters on the same tower couldn't hear well. That only took 'em about 10 years to figure out. Then, about 10 years after that, they started using gasfets, and it took them another 10 years to figure out they didn't do well in high rf fields. By then, it was the 1980's.....but at least they got it right eventually.

Maybe you designed some of those early nightmarish radios yourself?

Anyway, I wish you luck. And hope you realize the importance of keeping the front end clean, which sometimes means dumping the gasfet and using a bipolar preamp instead.

Actually, I hope the original poster (A*s*i*m*o*v) got the message about introducing gross non linear back to back diodes across the antenna terminals.

Have fun.

> happens to be free (as in beer).

Well, there are a couple of things here.

First of all, Microchip was early to the game. As a result, there is a lot of tutorial information out there. Admittedly, a lot of it is really bad, but it's existence helps people get over the hump. And lets face it, deploying a microcontroller really isn't very hard, but getting over the initial fear is. The huge number of PIC projects out there helps people feel like maybe it isn't so hard.

A second part is the really wonderful simulation capabilities of MPLAB. It makes it pretty darned easy to see what is going on, and when people are starting out, that is a pretty big deal. If you look at the hobbyist project code out there, it looks like 90% or more of them are written by people "just starting out".

Thirdly is the availability of cheap programmers. Yes, I know the AVR is even simpler to program than the PIC, but it hasn't drawn literally hundreds of programmer designs, almost all of which can be built cheaply. This is another consequence of Microchip being early to the game.

And actually, I think an advantage the PIC has is that, at least for the 16F PICs, all the C compilers are truly horrid. When you are going to deploy a microcontroller, any microcontroller, you really need to understand what is happening at a pretty basic level. Once you have a lot of expertise in a particular part, then a compiler can be a big productivity boost. But until you have a lot of expertise, the compiler can really get in the way. Fortunately for the PIC community, most of the compilers are bad enough that you're not real tempted to use them.

> Actually the AD9850 comes in a SOIC package with 20 pins/inch, or half

I've never seen a 9850 in an SOIC. That certainly would be easier to use. Where did you find such a thing? When I check AD's web site, all I see is a choice whether I want my SSOP's on a reel or not.

We are talking presynth. I had my First Class before that.
My first commercial UHF repeater was built from U44 components then
later Motrac as they were current radios For 1971-2 that was pretty
good. The motrac front ends were 6 cavitys a mixer then IF
selectivity, crunchproof. LO was always a crystal for least phase
noise. Anyone that read papers by Rhode understood this in the
early to mid 70s.

>Maybe you designed some of those early nightmarish radios yourself?

I take that as insult. ;) Gads no, I thought they were crap too.

I'm not all that thrilled with the ARC308C or worse 324 and the put
them in planes. I know that as I have a 308 as backup. Gag, Ick,
ick. but at 1500 to 2k for a new one I'll keep it till it quits.

>Anyway, I wish you luck. And hope you realize the importance of
>keeping the front end clean, which sometimes means dumping the gasfet

>and using a bipolar preamp instead.

Your being pendantic again.

I'm not big on gasfets untill I get above 1GHz. At 6m a u310 bipolar fet in common base gets me about 12db. With a good IP and noise figure. Just enough to get past the image stripping filter before the Level-7 DBM. That makes for a nice crunchproof frontend that with sub 3db noise figure. If I could get that noise figure without the fet I'd not use it but I need the gain. I've tried mrf571 in a norton push pull configuration, hard to overload but the 100ma standing current was hard to take for portable ops!

If your interested, ops here are QRP weak signal 6m SSB and 2M ssb and occasionally CW using solar power and battery. Power consumption is a consideration as well as perfomance. Overload performance with a KW 800ft away and in band is well challenging. The challenge is to get enough gain to ovecome the mixer noise without having a watt of power at the mixer.

>Actually, I hope the original poster (A*s*i*m*o*v) got the message
>about introducing gross non linear back to back diodes across the
>antenna terminals.

That is true. However think about it for more than a second. Diodes or not hes talking about gain, bandwidth and noise so even without the diodes hes already running wide and risking overload at the next stage. Without selectivity you get cascade overload. The classic problem of weak reciever fix of stacking gain before it and watching the input overload threshold wander in to the -40dbm (or worse) region. Bad way to fix the problem.

TR> Have fun.

I have followed both your points with great interest. My guess is that the diodes are benign in a weak signal area. I expect the original design used them more for static rather than for overload protection because the input was intended to expect microvolt levels.

My choice would be not to use anti-parallel diodes in a design but this is what I found in the circuit so some engineer thought about it enough to use them. I would have preferentially used a reverse biased diode across the active device's junction because it is usually the reverse polarity in a pulse that damages a junction.

In this question I was more interested on the effect of the protection diodes' capacitance because as you know it is greatest at zero bias. This wideband pre-amp's input stage uses feedback to define the input impedance and the diodes' capacitance is at the node point, so I wondered if there was little effect. As you know, in an inverter the node point is ideally a voltage null.

Thank you both for the great debate!

That's the cool thing about AVR-GCC, though... you really *don't* need
to understand what is happening at a fundamental level. It just plain
works. I've used AVR-GCC chips in a half-dozen projects, some of them
very non-trivial, but I wouldn't know a line of AVR assembly if it bit
me.

It certainly doesn't hurt to master your platform's assembly language,
especially if you need every bit of performance the chip can deliver.
But as long as we're talking about hobby applications, I think most of
us can agree that life at the bench is too short to spend it learning
various proprietary assembly languages for no good reason.

Sorry; you're totally right -- it's not a SOIC, but an SSOP with 0.65 mm
pitch (39 pins/inch).

I've only used the AD9850 in one project, and I've never actually
ordered one -- I lifted mine off an old PC-VFO ISA card from 1998 or so.
Seemed to remember it being a SOIC, but the photos at archive.org show
that it definitely was not. There are other SOICs on the PC-VFO board,
and they have a coarser lead pitch than the DDS chip.

The AD9852/4 chips have the same 0.65 mm pin spacing for the record, but
a heck of a lot more pins. :)

I use DigiKey #K439-ND dispenser tips with 0.016" hole. They screw
onto the end of the paste syringe. Works great. I don't hot-air refow,
but it allows for a small-volume dispense.

My technique is to run a bead down the center of the row of pins, and then
heat each pin briefly, or all at once if I have a proper tip for my Metcal
station. The solder wicks up to the pins, and there's maybe one bridge on
a 48-pin TSSOP.

Done it for years this way.

Generally a good design and a robust device will be tougher than the
diodes frequenty used.

For example I've found JFETS will easily stand 40+volts on the gate
before failing, MOSFETS (dual gate 3n200 types and BFR998) 60-80V
were needed to kill them. Even a lowly 2n5176 bipolar will be grossly
overloaded in a wide band amp before possibility of destruction.

Remember .5V PP (I'll assume silicon diodes) is at or around -1 to
0DBm. Thats one milliwatt of RF. the real issue is with wide band
signals you can have multiple signals within the bandwidth that at
some point in the cycle are additive and as we've all said those
diodes will do bad things under those conditions.

The capacitance if of limited significance. Its' effects will be
tempered by topology and impedences at the point of use.
As pointed out, they must not see conduction or "bad things happen".

_IF_ you really must protect the input with diodes put a healthy
(6-12V) of reverse bias on them. That should adequately protect
the first device but still absorb transients.

For instrumentation applications (high impedence) they are a
commonplace thing as the source could be anything or known.

For RF use I tend to leave them out as most devices once in circuit
are robust as is. And usually uf there is an event big enough to fry
the device then protection diodes are just two more fried devices.

One exception: series diodes on the supply for reverse polarity
protection and Zeners(or transzorbs) on the supply for overvoltage

protection. Often destruction didn't come down the antenna but in the back door via the power or other control lines.

>Thank you both for the great debate!

As in most electronics there are subtle and gross effects. Being aware of both are of importance. Hope it helps.
